THE CARE OF AUTOMOBILE INJURIES INVOLVING THE FACE*

GORDON B. NEW, M.D., and JOHN B. ERICH, M.D.

Rochester, Minnesota

IN recent years, motor accidents have become so common that nearly every clinician, whether internist, surgeon, or specialist, is called upon in one capacity or another to treat patients who have been injured in automobile accidents. When such traumatic wounds involve the face, the effects of treatment are usually of particular interest to the patient, since in this region the esthetic outcome is as significant to him as is the functional result. The more or less popular opinion that the majority of traumatic facial injuries which are vital neither to the life of the patient nor to the functions of the body are inconsequential and therefore deserving of little immediate consideration is a misconception. On the contrary, it has been our experience that many patients are so concerned with post-traumatic deformities of the face that emotional disturbances develop. In short, the end-results of the surgical management of facial injuries affect not only the final appearance of the part involved but ultimately the patient's mental and emotional processes as well. This fact bears emphasis and should stimulate the surgeon to give every primary facial wound, no matter how insignificant, careful attention in an effort to prevent or minimize subsequent disfigurement.

A complete discussion of the care of automobile injuries involving the soft and bony tissues of the face is entirely too broad a topic to consider in these few pages. In consequence, we are forced to disregard technic and details for those general principles which we have found

useful and essential in the treatment of such injuries. Furthermore, it is well to remember that no amount of minute elaboration can alter the fundamental character of these principles. It is true that a great many of these injuries require some form of individual consideration and a few necessitate the construction of special appliances. However, without a knowledge of the underlying principles which govern the treatment of automobile injuries of the face, it is certain that the surgical management not only will usually be ineffective but also will continually become less inviting.

The care of automobile injuries of the face may be divided into primary and secondary treatment. The former refers to the initial wound; the latter, to facial deformities which may follow the original injury. We are confident that the immediate repair of traumatic wounds of the face is distinctly advantageous. It stimulates prompt healing, limits the degree of inflammatory reaction and, in turn, minimizes the subsequent scarring. However, early treatment does not infer the employment of hasty or careless time-saving methods which some surgeons seem to regard as emergency measures. No doubt many facial deformities and subsequent plastic operations could be avoided if more care and time were given to the treatment of the primary injury. It is safe to say that the more time spent in precise execution of each detail of surgical technic, the more pleasing will be the ultimate result.

In certain cases, it is neither possible nor always advisable to care for the wounds immediately (Figs. 1a and 2a). Treatment of serious

and complicated fractures of facial bones, in which there is much displacement of the fragments, is preferably postponed until satisfactory roentgenograms can be secured; if the fractures involve the jaws, dental roentgenograms and dental plaster of paris study models are frequently necessary as well. Only with such accessory diagnostic agencies and only after a great deal of preoperative planning can one accurately determine the best method of reducing the fractures and immobilizing the fragments. A patient who is in shock should be put to bed and surgical intervention, other than such measures as are necessary to control bleeding, should not be instituted until his condition improves. There also are those cases in which the general condition of the patient is so critical, owing to associated injuries or to a fracture of the skull, that it is not in accordance with good judgment to attempt any type of immediate treatment of the facial wounds. However, if possible, the soft tissue injuries should receive attention within a few hours after the accident, while management of any fractures of the facial bones is better deferred indefinitely.

In cases in which there are lacerations about the face, hydrogen peroxide is a most effective agent for the removal of débris and coagulated blood; it leaves the injured tissues clean and fresh. The ultimate formation of scar tissue in any wound is always diminished by sharp excision of ragged or macerated margins. Portions of skin in which the blood supply is so poor that sloughing is virtually assured should be promptly removed. However, in many instances it is surprising to observe how a comparatively narrow pedicle will maintain the vitality of a rather large dermal flap. Since the formation of a hematoma is most undesirable, it is extremely important that a wound never be closed before the bleeding has been completely controlled by ligating every vessel which continues to ooze. In the repair of lacerations, we employ a minimal amount of chromic catgut to bring together the subcutaneous tissues and interrupted sutures of fine silk to approximate the edges of the skin (Fig. 1*b*). The use of heavy dermal sutures which include large amounts of tissue is to be condemned because they produce a great deal of unnecessary scarring. Neat, meticulous suturing and ample drainage are essential in securing a

satisfactory cosmetic result. In large undermined wounds, we prefer Penrose drains, but in those of smaller dimensions we use ordinary rubber bands; the latter make excellent drains and leave but little scarring on removal. Very superficial lacerations, after being cleansed, may be safely closed without any form of drainage. Of the utmost significance immediately after suturing a wound is the application of a pressure dressing which should be left undisturbed for at least forty-eight hours; this further obviates the possibility of the formation of a hematoma.

Regardless of the absence of gross contamination, every open wound sustained in a motor accident undoubtedly is invaded by pyogenic bacteria. However, with proper care, lacerations about the face of healthy individuals rarely show clinical signs of infection. By the phrase "proper care" we do not allude to the use of any type of antiseptic solution, but refer to such measures as débridement of the wound, complete hemostasis, adequate drainage and prevention of a hematoma. Probably no factors so favor the development of active infection in a wound as does the presence of a hematoma or the lack of sufficient drainage. Although, with appropriate management, infection of facial injuries is remote, every physician continually encounters suppurating, traumatic wounds in cases in which patients do not seek treatment early. In these cases, we adopt a most conservative regimen of therapy; we leave the wounds entirely alone except for the continuous application of hot, moist dressings until the acute inflammatory process has subsided. Recognition of the potential seriousness of a hematoma should prompt one to remove such a blood clot thoroughly from any wound whether or not the latter has been previously sutured.

Losses of tissue are frequently observed in automobile injuries about the face. In properly selected cases, such wounds afford great opportunity for the use of plastic procedures. When a small portion of skin is missing, if the margins of the defect are deeply undermined by sharp dissection, a gratifying closure can be obtained. In cases in which a large amount of skin has been lost, such treatment can only result in much distortion of the involved part; in these cases the immediate application of a skin

graft is an excellent procedure, provided that gross contamination is not evident. If the denuded region is not too large, dissected dermal grafts from the upper eyelid or the posterior

the resultant deformity; the wounds are left open for several weeks until healing is complete and until the subsequent inflammatory thickening and induration have entirely disappeared.

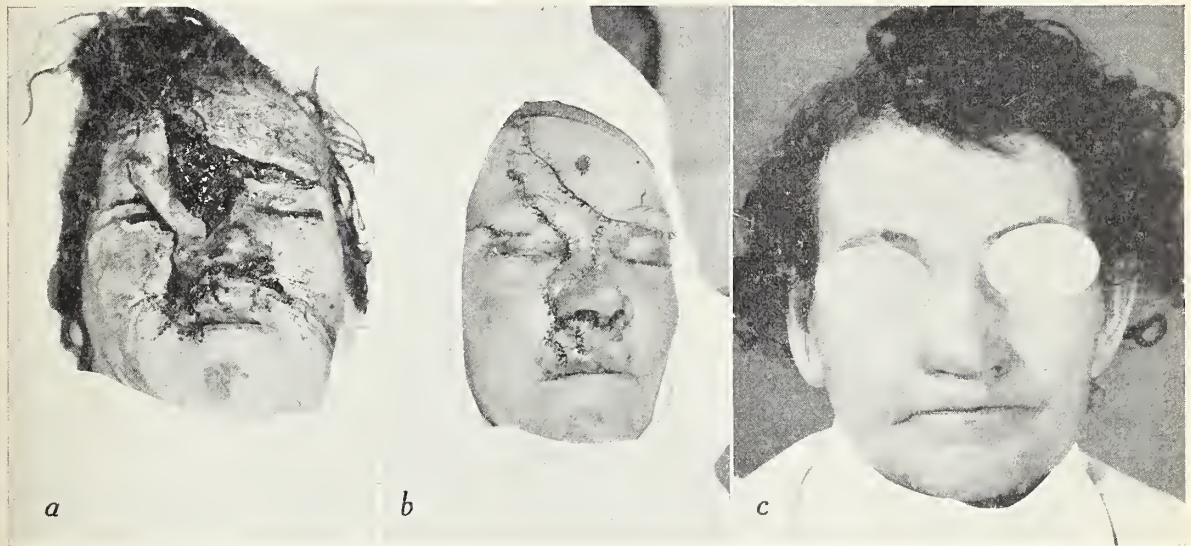

Fig. 1 *a*, Laceration of face and badly comminuted fracture of nasal bones of a guest passenger who was thrown against the windshield of an automobile; treatment was postponed for eight hours because the patient was in severe shock; *b*, photograph taken after the lacerations were cleansed and sutured; one Penrose drain and several rubber-band drains were used; the skin was closed with interrupted sutures of fine black silk; *c*, photograph taken six months after treatment of the injury; a cartilage implant will be required to correct the deformity of the nose.

auricular region are preferable because the color of the skin obtained in these situations very closely resembles that of the rest of the face. However, when a large graft is required, one is forced to resort to the employment of a dissected or shave transplant taken from the inner aspect of the arm or thigh. The act of adapting a dermal graft to a region recently denuded of skin is usually met with considerable success, and thus scarring and distortion are prevented which is inevitable when such a wound is left to become epithelized spontaneously. In badly contaminated wounds, of course, skin grafting is entirely out of the question. Instead, we apply warm dressings and defer the transplantation of skin until the infection has entirely disappeared. It cannot be doubted that were skin grafts employed more frequently the cosmetic result in many traumatic wounds of the face would be greatly enhanced.

The immediate repair of such defects as the loss of an extensive portion of the lip, cheek, nose or eyelid is impossible. Fortunately, such frightful injuries are relatively uncommon. In these cases, we elect to disregard temporarily

Then with the use of one of the delayed pedicle or tubed flaps, which was illustrated in figure 1 in an article which we wrote recently⁴ reconstruction of the missing part may be undertaken. Owing to the limited length of this paper, a discussion of this type of reparative surgery cannot be attempted.

To the surgeon and patient alike, deep facial lacerations in which the seventh cranial nerve or the parotid duct has been severed are most distressing. The former injury results in a facial palsy, the latter in an external salivary fistula. Should the main trunk of the facial nerve be divided, an endeavor should be made to suture the cut ends. If this procedure does not induce regeneration of the nerve, then the problem becomes one for the neurosurgeon. Less serious is the severance of the peripheral fibers of the seventh cranial nerve, many of which will eventually regenerate. Occasionally, as previously indicated, a penetrating laceration of the cheek will include Stenson's duct and result in an external salivary fistula. To direct the flow of saliva into the mouth rather than through the fistula, we favor the method of

Glascoek. Briefly, this procedure involves the use of strands of silkworm-gut which are inserted from the oral cavity through both distal and proximal segments of the duct and which

that is, the frontal, nasal, maxillary or malar regions. In spite of the fact that the driver is able to brace himself against the steering post and thereby ward off much of the brunt of the

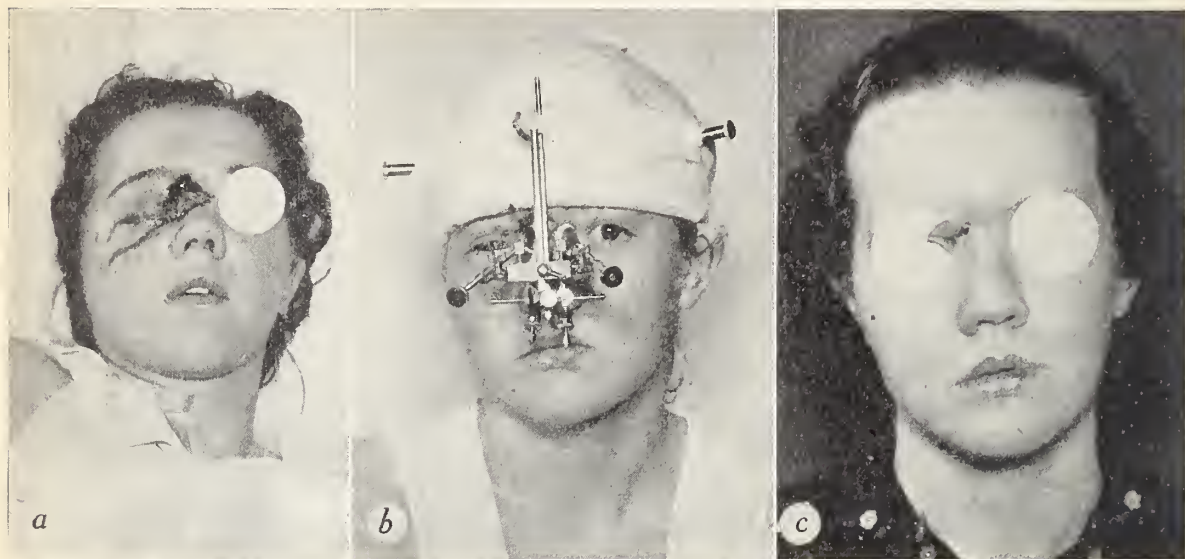

Fig. 2 *a*, Injury of the frontal region which exposed the frontal sinus and fractured the frontal nasal and maxillary bones and the malar bone; treatment was not instituted until ten days after the accident, for fear of inducing meningitis; *b*, photograph of patient taken after completion of initial treatment; right malar bone was elevated by intra-antral manipulation and immobilized by an intra-antral iodoform pack; the fragments of the comminuted nasal bones were molded into their correct position and immobilized by the apparatus shown; this has two wires which hold the nasal bones forward and has two lateral adjustable pads which produce pressure on the sides of the nose and keep the bridge narrow; *c*, photograph of patient taken six months after initial treatment.

finally emerge on the external surface of that portion of the cheek which overlies the parotid gland. A Penrose drain passed from the mouth to the lacerated region, through a stab wound adjacent to the distal part of the duct, is of great value in carrying away the excess of saliva. The external wound may then be tightly sutured. Such management encourages the flow of saliva to follow the Penrose drain into the mouth and opposes the development of an external salivary fistula. Serving as a framework along which epithelization can occur, the strands of silkworm-gut assist in restoring the normal continuity of the duct.

In automobile wrecks, it has been pointed out by Straith that passengers riding in the front seat not only are more frequently injured than is the driver but are subject to more serious injuries. Since the guest passenger lacks the support of the steering wheel, during the impact of a collision he is thrown violently downward as well as forward against the instrument panel or the windshield. His injuries are likely to involve the upper half of the face,

impact, his head may strike the steering wheel with considerable force. His resultant injuries usually involve the lower part of the face, mainly the chin and mandible.

The nasal bones are more often fractured than are other bones of the face. The treatment of simple nasal fractures is well known. Internal or external manipulation is all that is required to reduce these fractures, and, generally, no means of fixation is needed. In some cases, an intranasal pack or an external splint is necessary to maintain the nasal bones in proper alignment. Occasionally, in severe fractures of the nose, the nasal bones are badly comminuted and driven back into the ethmoid region. In such cases, owing to the probability of an associated fracture of the ethmoid bone, manipulation of the nasal bones should be postponed at least ten days for fear of inciting the development of meningitis. When the nasal bones are severely comminuted and depressed, it is useless to elevate them unless some form of fixation is available for holding the bones in the desired position. We have made an instrument which

possesses all of the necessary mechanical requirements for supporting the nasal bones in correct alignment; its principle is not original with us, but its design has been changed to suit our needs. This appliance is attached to a plaster head cast and has two wires which are inserted in the nostrils for elevating and immobilizing the nasal bones (Fig. 2b). In addition, it has two adjustable pads which maintain lateral pressure to keep the bridge of the nose narrow. In many of our cases, this instrument has proved its value in the final result (Fig. 2c).

The great majority of permanent nasal deformities following automobile accidents are due to neglect of the primary nasal fracture or are the result of poor immediate treatment. However, in an occasional fractured nose, even after the utmost care has been taken to restore the nasal bones to their original position, some deformity persists. If a patient wishes his nasal deformity corrected, it is preferable to wait at least six months after the accident before attempting a plastic repair. The most common traumatic nasal deformities are the crooked nose, which may deviate to one or the other side and which is usually associated with a deflection of the septum, the hump nose in which the nasal bones are abnormally elevated, the bulbous or broad nasal tip in which the lower lateral cartilages are markedly flared, the saddleback nose in which the nasal bones are depressed, and combinations of the foregoing deformities (Fig. 1c). The first three types of deformities are remedied by intranasal operations; displaced nasal bones are refractured and molded into their proper position; a prominent hump is removed by means of a saw or chisel and mallet, and a broad tip is corrected by readjustment of the lower lateral cartilages. Marked deflection of the septum which produces symptoms of nasal obstruction should be corrected by means of submucous resection; this operation should be performed three or four weeks in advance of the nasal plastic operation. When a saddleback deformity exists, the normal contour of the nose can be restored by means of a cartilage or bone implant. If the nose requires no treatment other than the insertion of the graft, we prefer to use bone obtained from the crest of the ilium, but if the deformed nose requires refracturing or some other form of manipulation or if there is any possibil-

ity of infection, cartilage is a more desirable tissue to transplant since its innate qualities to withstand infection or an inflammatory process are superior to those of bone.

Malar bones are often fractured in such a manner that they retain their continuity with little or no comminution. In these cases, the fractures occur along the normal suture lines, that is, through the frontozygomatic suture above, through the temporozygomatic suture laterally and through the inferior orbital foramen below. The bone is generally depressed downward and backward. Without the aid of a roentgenogram, there is often difficulty in the diagnosis of such a fracture because of the excessive swelling of the overlying soft tissues. Roentgenograms are absolutely essential, and we prefer a vertical profile view, the rays being directed from the chin toward the vertex. Such a roentgenogram shows very nicely the relative position of the two inferior orbital margins and the degree of displacement of malar bone on the involved side. When there is no comminution of a fractured malar bone, treatment is not difficult. A steel hook, inserted through a small incision in the skin, is an effective method of elevating the displaced portion of bone into position. The hook may be introduced so as to grasp the lower border of the fractured malar bone or may be inserted along the floor of the orbit to the inferior orbital fissure. Considerable force is necessary at times to bring the fragment into correct position, but, with few exceptions, no form of fixation is required. When a malar bone is badly comminuted and there is involvement of the wall of the maxillary sinus, we recommend reducing the fractures by an intra-antral operation. An opening is made through the mouth into the maxillary sinus, and by finger pressure within the antrum, the fragments are manipulated into their correct position. For immobilization, an iodoform pack is inserted within the maxillary sinus and left in place until the fragments have united, a period usually of about three weeks.

Ocular palsies resulting from injury to the floor of the orbit are unfortunate complications of fractured malar bones. Manipulation of the fragments from within the maxillary sinus will sometimes correct the ocular disturbance, but in many cases it is not possible to reduce the

fractures so that the extra-ocular muscles will function normally; in such instances, the ocular palsy remains a permanent condition. Enophthalmus, another complication of some fractured malar bones, is disagreeable and incurable. The floor of the orbit may be so badly comminuted and depressed that the eyeball will drop down a few millimeters owing to lack of support. If manipulation of the fragments does not elevate the globe, a cartilage implant along the floor of the orbit will often overcome the deformity. However, in some cases even a cartilage implant is ineffective in restoring the eye to its proper position in the orbit. A depressed fracture of the malar bone which is left untreated will produce a flattening of the involved cheek. Attempts to correct this deformity by refracturing the bone and manipulating the fragments into their proper position are usually met with little success. In these cases, we believe that symmetrical proportions of the two cheeks can be secured most easily by the use of a cartilage implant to build up the depressed region on the injured side.

The treatment of any fractured jaw is successful only when the continuity of the bone has been established and when the normal masticatory mechanism has been restored. The fragments of a fractured jaw may be firmly healed by bony union, but the end-result is a failure if the original occlusion of the teeth has not been reestablished to insure normal mastication. No single word has greater significance in any discussion on fractures of the jaws than does the term "occlusion." Nearly every fracture of a jaw in which there is the least displacement of the fragments causes some disturbance of occlusion, and unless the teeth can be brought into their normal relationship the fragments will not be restored to their original position. No factor serves as a better guide for determining the position of the fragments than does the occlusion of the teeth. Frequently, in cases of fracture of the jaws, it is almost impossible to tell by visual inspection of the mouth what relationship actually existed between the upper and lower teeth before the fracture occurred; this may be the result of loss of many teeth in each dental arch or it may be due to primary malocclusion of the teeth. In these cases, the preparation of plaster models of the dental arches will

materially aid in determining the original form of occlusion. It can be said that fractures of the jaws cannot be satisfactorily reduced unless one is certain of the original position of the teeth in each individual case.

Innumerable methods of reduction and immobilization have been described in the treatment of fractured jaws. Each has advantages and disadvantages; each is adaptable to certain types of fractures. No one method is suitable for every case. A few produce excellent results in the hands of some surgeons but not in the hands of others. Consequently, it is a mistake to attempt a comparison of the various methods. It is our opinion that those procedures with which the surgeon is acquainted and finds satisfactory are the methods he should employ.

It is a generally accepted fact that open operations for the reduction or fixation of fractures of the jaw usually are disastrous and only result in infection, necrosis of bone and ultimate loss of union. One must rely on intraoral procedures for the care of fractures of the mandible and maxilla.

The great majority of fractures of the maxilla that we see at the clinic are transverse (horizontal) in character. The entire upper jaw is freed from the rest of the skull and is usually pushed upward and backward. This injury results in an open-bite type of deformity which makes mastication impossible. The principle of treatment of a transverse fracture of the maxilla is to reduce the fracture so that the teeth of the upper dental arch will occlude normally with the teeth of the lower jaw. Regardless of how freely movable the fractured upper jaw may be, it usually is not possible to manipulate the maxilla into its correct position manually. To secure good occlusion of the dental arches in a case of transverse fracture of the upper jaw, one must rely on elastic traction as a means of reducing the fracture. We first wire arch bars to the upper and lower dental arches. This is followed by the application of a plaster cast to the head. A rubber band passed from the upper arch bar to a rod that is fixed to the head cast will pull the upper jaw forward. Vertical rubber bands stretched between the arch bars pull the teeth of the maxilla downward into occlusion with those of the mandible. When the upper jaw is freely movable, traction wires for

immobilization are attached to the upper arch bar, passed through the cheeks, and fixed to adjustable hooks on the head cast after the method described by Federspiel. In cases in which

gion on the involved side (described by Ivy, Fig. 3*b*). A wire inserted through the posterior fragment and rubber band stretched from this wire to the hook will pull the posterior frag-

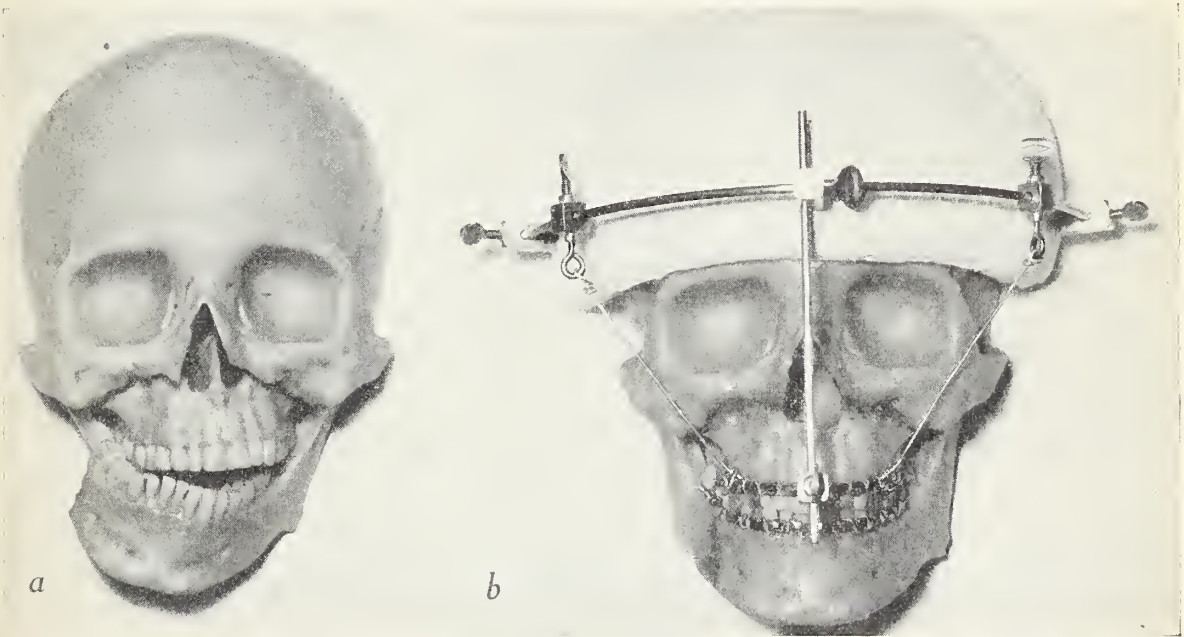

Fig. 3 *a*, Wax moulage of skull of patient injured in an automobile accident, showing fracture of right body of mandible and a transverse (horizontal) fracture of the maxilla; *b*, wax moulage of same patient; the fractures have been reduced by intermaxillary wires attached to hooked arch bars; the upper jaw has been immobilized by two traction wires attached to the upper arch bar, passed through the cheeks, and attached to adjustable hooks on a plaster head cast.

the maxilla is edentulous, the traction wires are fixed to an artificial denture worn by the patient.

The use of intermaxillary wires, arch bars and rubber bands, the ribbon arch mechanism, and the edgewise arch mechanism in the treatment of simple fractures of the mandible is well understood. We recommend that a dental root in the line of fracture should be removed unless it is the only tooth in the posterior fragment. In such a case, it is well to preserve the tooth for fixation of the fragment. When but one tooth is present in a fragment, we generally apply an orthodontia band to this tooth so that it can be used for immobilization. When the fracture of the mandible is situated behind the third molar tooth (Fig. 3*a*), the posterior fragment is often displaced forward and upward by muscular traction. To reduce this type of fracture, we first wire the teeth in occlusion in order to fix the anterior fragment; next, we apply a head cast in which is incorporated a hook that emerges in the posterior auricular re-

ment back into proper position. Many of the mandibular fractures which we see are several weeks old and in such cases elastic traction is essential in reducing the fracture. Subcondylar fractures are better left alone except for wiring the teeth in occlusion for a period of three or four weeks. If the condyle is displaced, its removal or replacement is contraindicated; we have never seen such a case in which the disturbed condyle interfered with the normal movements of the mandible. In cases of fracture of the horizontal ramus of the mandible in which the patients are children, we prefer to use a cast silver bite splint which can be cemented to the teeth of the lower dental arch; by means of circumferential wires passed around the mandible and fixed to the casting, the lower jaw is thoroughly immobilized. This gives the child free mobility of his jaws during the healing period.

An edentulous mandible which is fractured anterior to the third molar tooth on either side may be nicely immobilized by the use of circumferential wires attached to a lower artificial

denture. However, if the fracture is situated behind the second molar tooth, a Gunning double-arch splint is required; should the posterior fragment be pulled forward by muscular traction, a wire inserted through this segment of the bone and fixed to a head cast may be necessary to maintain this fragment in its normal position.

In conclusion, we would like to mention two uncommon but potentially possible complications of every fracture of the jaw. The first is non-union of the fracture; the second is an osteomyelitis with sequestration and loss of bone. When either one of these conditions involves the mandible, a repair can be accomplished only by means of a bone graft. For this purpose, we elect to use bone obtained from the crest of the ilium. Before the insertion of such a graft, it is most important to immobilize both fragments of the mandible thoroughly. After exposing the free ends of the fragments, the bone is cut to the desired shape and is inlayed and fixed between the two fragments. In these cases, one may anticipate good results if the oral mucous membrane is not accidentally incised; even a small nick insures infection of the wound by the entrance of secretions from the mouth.

An analysis of post-traumatic deformities of

the face has confirmed our belief that many such defects could be prevented if only the surgeon would devote more time and give more consideration to the primary wounds. To obtain satisfactory cosmetic results in the treatment of facial injuries sustained in motor accidents, we desire to emphasize the significance of early treatment of proper débridement of the wound, of complete hemostasis, of adequate drainage, of the use of a minimal amount of catgut, and of the insertion of fine skin suture material. Much unnecessary scarring and disfigurement of the face can be prevented by the immediate application of dermal grafts to large regions denuded of skin. Finally, in the management of fractured facial bones, we wish to stress the importance of careful preoperative planning, which aids materially in surmounting those difficulties and discouraging problems that unavoidably arise in the care of these injuries.

EYE INJURIES DUE TO MECHANICAL CAUSES*

D. L. TILDERQUIST, M.D.

Duluth, Minnesota

THIS paper deals with injuries of the eye due to mechanical causes. It aims to present a few simple principles which may aid the physician who first sees an eye injury to determine the approximate severity of such an injury.

In any injury to the region of the eye due to mechanical causes, swelling of the soft parts around the orbit and of the lids, and wounds of these parts, will be evident at once. Marked swelling and distortion of the soft parts may hide a possible fracture of the bones of the face, of the nose, or of the orbit. When the swelling subsides it may then be discovered that there is a bony deformity, which by that time may be very difficult to correct. Since the zygoma is a

prominent structure of the face, a blunt, severe blow may fracture it without causing any other bony fractures. There have been two instances in our practice in which this has resulted from a blow of a fist. A fracture and displacement of the zygoma should be detected by bony deformity of the face, by notching of the rim of the orbit, and by a displacement of the eyeball due to encroachment upon the orbital contents by the displaced bone. The x-ray is our best single means of diagnosing this condition accurately. If nothing is done, the displaced bones may cause interference with the action of the extraocular muscles, or cause other disturbances in the functioning of the eye. A displaced zygoma can nearly always be replaced to a normal position, if the

*Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 1, 1939.

attempt is made within a few days, or not more than a week after the injury.

Wounds of the lids involving the margins of the lids should be repaired at the earliest possible time, for if allowed to heal without careful replacement of the parts, deformity of the lids is apt to occur. This is very difficult to correct after the parts are scarred and contracted.

The conjunctival sacs and the eyeball should be inspected if possible at the first examination. At such an examination, no elaborate instrumentarium is called for. A good flashlight, if nothing else is available, is splendid for this purpose. A solution of 4 or 5 per cent cocaine, instilled between the lids after these have been cleansed carefully, will often be of great advantage. A lid elevator is also useful, but a small smooth hook, or any small smooth instrument available, may be used to lift the lids if this procedure should be necessary to aid in the examination.

The cornea, the conjunctiva, and the conjunctival sacs should be inspected for wounds, bruises, areas of subconjunctival hemorrhage, and for foreign bodies. Injuries to the cornea are detected by a cloudiness of the cornea at the site of the injury, and by a break in the continuity of the normal reflex of the surface. Even if the lids are greatly swollen, all parts of the cornea can be brought into view through a very narrow opening between the lids by having the patient shift his point of fixation with the other eye. The presence of a foreign body can usually be suspected by the history of a scratching or of sharp pain on movement of the eyes. Pieces of glass are sometimes the most difficult of all foreign bodies to find, for their transparency increased by the moisture of the tears sometimes hides them very effectively. It is often a good plan to have the patient localize as exactly as possible the site of the pain or tenderness before any local anesthetic is instilled, for after that this means of localization may be gone.

Any manipulation about the eye, however, should be carried out with the utmost gentleness, for the damage resulting from a serious injury, such as a perforating wound of the eyeball, can be increased greatly by rough and careless handling of the eye.

There is one simple test which helps a great deal in determining the seriousness of any injury to the eye, and that is the determination of the

acuity of vision. This can be carried out quite easily if the patient is in such a condition that co-operation is possible. It need not be done with any degree of refinement but may be done roughly by the reading of the letters of any printed matter at hand, by the counting of fingers, by observing hand movements, or finally by the recognition of light. One must be sure that the vision is not obscured by external causes such as swelling of the lids, blood, or even tears between the lids. Marked photophobia is often present, and this may interfere.

If the vision is not reduced but seems to be the same as that of the other eye, there is a fair degree of assurance that the eye is not severely injured. If there is a definite reduction of vision of an eye the injury should be considered serious, at least for the time being.

Injuries to the eyeball may be either non-perforating or perforating. Non-perforating injuries may or may not be serious. If the causative blow has not been severe, the eye may rapidly become free of symptoms. A hard blow may cause severe internal injuries to the eye such as rupture of the iris, of the lens, detachment of the retina, et cetera, or rupture of a blood vessel causing intraocular hemorrhage.

A non-perforating injury may give no special findings on inspection beyond more or less congestion of the eyeball. A dilated pupil, or a displaced pupil, for which there is no other apparent cause, or a streak of blood in the anterior chamber, indicates internal ocular injury. A massive intraocular hemorrhage gives a very characteristic picture, a dark red, or sometimes altogether black, highly polished appearance of the cornea. Such a condition is always serious.

A perforating injury of the eyeball, no matter how small the perforation may be, is always a major injury on account of the possibility of infection, of injury to the delicate internal structures of the eye, and of the entrance of a foreign body. Any perforating injury carries with it the possibility of an eventual loss of vision, and even of the loss of the eyeball.

A perforation may be easily visible at first sight as a large gash in the cornea or sclera, or in both, through which iris, vitreous or other structures may be protruding. But if the perforation is small, it may be obscured by swollen conjunctiva or by blood-stained fluid and may

not be detected. A pear-shaped pupil is indicative of a perforation near the edge of the cornea with a possible incarceration of the iris in the wound.

In any perforation of the eyeball there is usually loss of aqueous through the wound with the consequent immediate reduction of the intraocular tension, and often with the complete collapse of the eyeball. Therefore, in any case in which there is a suspicion of a perforation, this may be determined by trying the tension of the eye with the tips of the two forefingers in the same manner as fluctuation in a suspected abscess is determined, using the other eye for comparison. Usually, the difference is so marked that even the inexperienced should be able to detect it readily in one trial. Again, let me emphasize the need for great gentleness in making this test in order that the damage to the eye may not be increased by the test.

There is one type of perforation in which this test is of no value. A very tiny perforation may be produced by a finely pointed instrument, or by a very tiny flying foreign body (usually a metallic one), so small that no intraocular fluid will escape. The tension of the eye then remains normal. The vision, too, may not be disturbed, depending on the part of the eye affected by the foreign body. It is a good plan to have roentgenograms taken of all eye injuries in which there is a possibility that small high velocity particles might be involved.

A few illustrative cases are appended. For the sake of brevity, only the positive findings are enumerated.

Case Reports

Case 1.—A. K., male, aged twenty.

Three weeks before this patient was seen he had had a collision with another player at a basketball game and received a blow on the left side of the face. He became unconscious and was so for upwards of fourteen hours. The face and the eye swelled up a great deal. At the time he was seen, the swelling had subsided considerably.

On examination, there was a depression of the zygomatic prominence, a notching of the lower rim of the orbit, and some degree of anesthesia of the skin of the left side of the nose. The skin surrounding the left eye was discolored. There was ptosis of the left upper lid, moderate protrusion of the eyeball and a paralysis of the external ocular muscles. The eye could be rotated only very slightly in any direction. The pupil was dilated, failed to react to light, and very slightly to accommodation. The media were clear, and

the fundus normal. Vision was 20/100; through a pin hole, 20/30.

A roentgenogram showed a fracture of the lower and lateral rims of the orbit, separation of the frontal and maxillary zygomatic sutures, and a complete transverse fracture through the small wing of the sphenoid bone just lateral to the sella turcica on the left.

In this case there was a paralysis of the third, fourth, and sixth nerves. It was believed that this was due either to an injury of the nerves by the fragments of bone in the posterior orbit, or to hemorrhage in the posterior orbit.

The loss of function in this instance was undoubtedly due to the injury; possibly to injury of the nerves from the fractured fragments. It is impossible to say if any improvement could have been obtained if the bony fragments had been restored to their normal positions, but the attempt should have been made.

Case 2.—M. L., male, aged thirty.

On January 11, 1938, while working with a road crew and using a pick on the frozen ground something flew into his right eye. His vision was immediately nil.

Examination at the office a few hours later showed a horizontal cut running through the cornea into the sclera for a distance of five or six millimeters, the edge of the cornea being about the middle of the cut. The pupil was oval with the apex pointing towards the cut, but there was no hernia of the iris in it. There was some blood in the anterior chamber. There was no vision, not even the recognition of light.

A roentgenogram showed a large foreign body inside of the eyeball.

In this case, it was very apparent from the very outset that there was an injury so severe, and the prognosis so hopeless, that there was no hesitation in recommending the immediate removal of the eyeball as the quickest and most effective way of recovery. Consent to this was refused.

The foreign body, which proved to be steel and magnetic, was removed from the eye. Tetanus serum was administered, and other measures taken to counteract inflammation and infection.

There was no return of the vision, and the eye was finally enucleated to avoid the possibility of sympathetic inflammation in the other eye.

Case 3.—P. K., male, aged forty.

In 1920, while hammering on a brake connection, something hit him in the left eye. Examination then had showed a small perforation of the lower lid, but no suspicion of anything further. The vision seems to have been clouded for a while and then became almost normal. In 1922, two years after injury, the vision began to fail quite rapidly. He visited an ophthalmologist, who found the iris rust-colored, a condition known as siderosis, and made the diagnosis of tiny piece of steel in the eye.

The fragment was removed (by the magnet?) but no promise was made of return of the vision. The

eye remained quiet, but with a vision limited to recognition of light until in January, 1938, when a glaucoma with a very high tension and with marked pain developed. On account of this the eye finally had to be enucleated.

I believe that, if this eye had been watched more carefully, and the vision taken several times following the first injury, it would have been found to have been reduced, and thereby given rise to a suspicion of something wrong in the eye in time to remove the fragment of steel before the eye had been ruined.

Case 4.—J. B., male, aged twenty.

On May 17, 1937, a companion shot a broken wire paper clip by means of a rubber band at the patient. One prong of the clip penetrated the upper lid of the left eye, stuck there and was pulled out by the patient. The vision, as the patient remembered it, was not disturbed. He visited an ophthalmologist after a few hours, who evidently did not think anything serious had happened for he instructed the young man to wear a bandage for about a week and then to return.

Everything went well until the third day, when the eye became inflamed and the vision somewhat reduced. The next morning the eye was very painful and the vision very poor. He came to our office on the fourth day. The eyelids of the injured eye (the left) were very swollen, the upper lid showed a very tiny red spot in the upper temporal aspect of the lid, which the patient stated was the point of penetration by the clip. The conjunctiva was red and congested, the cornea steamy. No wound of the cornea or conjunctiva could be seen. The pupil was contracted, the iris swollen and discolored, the media cloudy, and the eyeball tender. The vision was limited to recognition of light.

This was a severe, acute panophthalmitis, the evident assumption being that the infection had been introduced into the eye by the paper clip perforating not only the lid but also the sclera.

A hole in the conjunctiva as small as this is usually not visible. It may too be possible from the position of the puncture of the lid that the clip penetrated the sclera entirely posterior to the conjunctival fold, thus producing no mark whatsoever on the conjunctiva. As the puncture was likely about at the equator of the eyeball, it would not have been visible with the ophthalmoscope through the pupil. With a normal vision, a normal tension of the eyeball, the physician cannot be blamed for assuming that the injury was a harmless one. In retrospect the only circumstance that might have given rise to apprehension on the part of the physician would have been the fact that perforations of the eyeball occur very easily from small sharp missiles coming at great velocity.

In spite of all treatment, matters went from bad to worse, all recognition of light disappeared, the pain persisted, and the eye finally had to be enucleated to stop the pain and end the disability.

Case 5.—E. G., male.

On November 3, 1937, this patient came to the of-

fice stating that four days before, while hammering on a cold chisel in repairing a big chain, something flew from the chisel and hit him in the right eye. He believed that the eyelids were open at the time and that he was looking directly at the chisel. The object which hit him was apparently a large one for it gave him a blow so severe that he staggered and the pain almost made him faint. However, he recovered quite promptly and kept working that day and also the next day. Towards evening of the second day the eye began to be painful, and the vision became cloudy.

Examination of the right eye showed the conjunctiva of the eyeball to be reddened, mostly on the temporal side. The cornea was clear. The iris was somewhat swollen and its normal markings indefinite. There was a small amount of exudate in the anterior chamber. The eyeball was tender but tension was normal. The media were cloudy. The vision was reduced to recognition of light.

A roentgenogram was obtained and that showed a very tiny spot which might be from a foreign body in the eye, but after taking several films its presence was still a matter of doubt.

Here it is very evident that a more or less serious injury to the eye had taken place from the fact that the vision was very much reduced, and there was clouding of the media of the eye. This could happen from a blow from a large blunt object, but the presence of a tiny foreign body in the eye could not be ruled out. If there was a foreign body in the eye, it would in all chances be steel and magnetic. Two courses of procedure were here open: First, to make an opening in the eyeball, insert the tip of the magnet and search for the foreign body. In that case, if there were then no foreign body found, the manipulation would give added risk to the eye. If, on the other hand, a foreign body were present, and no attempt were made to remove it, the eye would become ruined. Second, to institute temporary conservative treatment and watch the eye very carefully for developments. The latter course was followed.

No serious infection in the eye occurred, and after two months the cloudiness of the eye had largely disappeared and some degree of vision had returned. It was then possible to examine the fundus with the ophthalmoscope. A very tiny black speck was found on the retina about ten millimeters below the disc. An incision was now made in the eyeball, the tip of magnet inserted, and the foreign body removed. The eye went on to eventual recovery and restoration of perfectly normal vision.

Case 6.—L. C., male, aged twenty-three.

On December 16, 1935, this patient was seen on account of an injury to his right eye which had been sustained two days before by a blow on the eye. He had not thought that the injury was very severe. His vision had remained good until the afternoon of that day, when it had suddenly failed.

On examination, the eye appeared reddened. The cornea of the eye showed a brownish black shiny.

color. There was no iris nor any other details of the interior of the eye visible. The eyeball was hard.

This eye presented a very evident intraocular hemorrhage—how extensive, it was impossible to tell. If it were limited to the anterior chamber only, then there might be some hope of saving the eye with some restoration of vision. If the blood filled the whole eye, the prognosis would be hopeless.

The eye was watched for a few days, then an incision was made into the anterior chamber, and an attempt made to wash out the blood. Some clots were removed but others still protruded through the pupil from the posterior part of the eye. Following the operation, treatment did not produce much result. The tension of the eyeball remained high. The eye remained blind, painful, and irritable, and enucleation was finally advised.

Case 7.—J. H., male, aged twenty-eight.

In September, 1938, this man was on a vacation trip in the lake region north of Duluth with a party of friends from out of the State. While out fishing, the hooks of a casting plug caught in the patient's right eyelids and right eye. Since it was impossible for the man's companions to remove the hooks, they cut the hooks off close to the eye with pliers, and then brought the patient to Duluth as promptly as possible.

On examination, it was found that there was a wound in the right eyebrow in which the end of a steel fishing hook could be seen. Another end of a hook was located in the right upper lid about 5 mm. above the lid margin. There was a cut five millimeters deep on the margin of the upper lid about the junction of the lateral and middle thirds. The eyeball showed a penetrating wound of the cornea three or four millimeters long in the upper temporal quadrant. Protruding in this was a tag of the iris and a little vitreous.

In spite of the distortion of the structures of the eye, there was a good recognition of light from all directions.

This case is reported to show that even in a very evident severe penetrating injury of the eyeball the outlook is not necessarily hopeless. The facts that some vision was present, and that the inside structures of the eye did not seem too much lacerated, gave some hope.

The patient was taken to the operating room. Very careful cleansing treatment was given, the hooks were removed from the lids, and the lid margin repaired. The protruding iris in the wound in the eyeball was excised, and both eyes bandaged. Tetanus antitoxin was administered, and a course of other foreign protein treatment given.

The eye showed no signs of infection at any time, which was remarkable, and the wound went on to rapid healing.

The patient was discharged from the hospital after twelve days, was allowed to return to his home, and was referred to a local ophthalmologist for further

treatment. A report at the end of December, 1938, over three months later, stated that the vision had become better all the time, and in November he had taken an examination for Civil Service and was accepted. He had found that he could use the eye for rifle shooting but not quite so successfully for pistol shooting.

Case 8.—E. C., male, aged twenty-eight.

On August 17, 1938, while riding in the front seat next to the driver, a collision with another car occurred and the patient was thrown against the windshield and sustained rather extensive cuts about the left side of the face, the nose, and the left eye. He was seen soon after by his physician, who repaired the cuts. On account of the marked swelling, no view of the eyeball was obtained. During the next three days the patient made no complaints excepting that at times he would have a sharp pain in the left eye. On the fourth day, the swelling had subsided somewhat, and the eyeball was inspected and a wound of the cornea was discovered. He was then referred for consultation. On examination, a perforating wound was found in the cornea near the center in which the iris had become incarcerated. There were no signs of infection. He recognized light from all directions. We were about to terminate the examination when, upon taking a final look into the conjunctival sacs, we found, much to our astonishment, a thin, flat piece of glass which happened to be curved so that it lay quite snugly against the side of the eyeball and was not readily noticeable. A roentgenogram revealed no sign of any intraocular foreign body, nor any fracture of bones. Since it was impossible to replace the protruding iris, it was cut off and the portion adherent to the wound was cauterized. The patient made a good recovery with a final vision of 20/30.

Here is illustrated the necessity of the earliest possible examination of the eyeball, and, too, even though one lesion may be found, a thorough examination for other lesions should not be neglected.

Summary

1. If the injury in the region of the eye is gross, always consider a fracture of the zygoma as a possibility. A roentgenogram will usually determine this.

2. Always inspect the eye for evident injuries to the eyeball, or for foreign bodies within the lids.

3. If there is a definite reduction of vision of the injured eye, consider the injury a serious one until the contrary can be ascertained.

4. If the tension of the eyeball is definitely reduced there is in all likelihood a perforating wound of the eye. A perforating wound of the eye is always a grave injury.

DYSPHAGIA*

N. LOGAN LEVEN, M.D.

Clinical Assistant Professor of Surgery, University of Minnesota Medical School
Saint Paul, Minnesota

DYSPHAGIA is a symptom which frequently brings the patient to the doctor. It is seen at all ages and must always be carefully considered even when the examiner feels that the patient has no organic lesion. It is better to regard a case as organic and find eventually that it is functional than to make the diagnosis of a functional disorder and then find, at a later less hopeful stage, that there is something organically wrong.

A brief explanation of the normal process of deglutition should precede a discussion of the causes of dysphagia. After the food has been placed in the mouth, chewed, and covered with saliva, the bolus of food is passed backwards to the pharynx by closure of the lips and pressure of the tongue against the palate. From the back of the tongue to the clavicular level the bolus of food is largely carried by negative pressure created when the hypopharynx is opened with the mouth, nasopharynx and larynx closed.¹ The food is thus tipped over the back of the tongue and sucked into the open mouth of the laryngeal pharynx and some distance down the esophagus. This initial impetus may carry liquids to the cardiac opening but solids usually are propelled by peristalsis. When liquids are swallowed with the head at a lower level than the rest of the body, each mouthful is propelled along the esophagus by peristalsis as in the case of deglutition of solids. The cardia of the stomach then relaxes and the bolus passes into the stomach.

These facts are mentioned because any defect in the act of swallowing from the opening of the mouth to receive the food to the final relaxation of the cardiac orifice leads to dysphagia of greater or lesser degree.

The cases of dysphagia may be placed in three groups:⁸

- A. Those due to pain.
- B. Those with mechanical difficulty.
- C. Those having nervous disability.

Dysphagia Due to Pain.—Infection or carcinomatous ulcerations of the mouth, tongue, tonsils, pharynx and larynx may make swallowing of even liquids difficult. Retropharyngeal abscess may be a common cause of dysphagia in children. One of the worst symptoms of advanced tuberculous ulceration of the larynx is the great pain on swallowing.

In the esophagus, foreign bodies, peptic ulcer or esophagitis may cause dysphagia due to pain.

Mechanical Causes of Dysphagia.—Inability to open the mouth because of trismus due to tetanus, affections of the temporo-mandibular joint or the muscles of mastication, and stenosis of the mouth due to caustics may make the ingestion of food difficult. Scarring, fixation or partial loss of the tongue result in considerable difficulty in swallowing. Lack of saliva may also be a cause of dysphagia.

Lesions of the palate such as congenital or acquired defects and new growths interfere with normal swallowing. Carcinoma of the pharynx may cause dysphagia early in its course.

In the esophagus, foreign bodies, congenital, benign and malignant strictures and perforation of the esophagus may block the esophagus. Compression stenosis of the esophagus by substernal thyroid, aortic aneurysms and mediastinal masses and hiatus hernias are similarly mechanical causes of dysphagia.

Nervous Causes of Dysphagia.—Facial paralysis (N. VII), pharyngeal paralysis (N. IX, X, XI), and paralysis of the tongue (N. XII) interfere with the well coördinated mechanism of deglutition. In myasthenia gravis, dysphagia is present as an early symptom.

The Plummer-Vinson syndrome called by some hysterical dysphagia¹¹ has often been included under the nervous causes of dysphagia. Kelly⁵ believes that spasm at the entrance of the esophagus is the primary condition. More correctly this dysphagia is part of a syndrome of hypochromic anemia occurring in middle aged women

*Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 1, 1939.

and probably due to chronic blood loss. These patients have glossitis, with atrophy of the mucosa of the mouth, tongue, esophagus and sometimes stomach, and often achlorhydria. In only 10 to 15 per cent of these cases does dysphagia occur.

There is another group of neurotic patients in which the dysphagia is purely functional. However, it should be remembered that there is no reason why a neurotic individual may not have an organic lesion in the esophagus.

The lesions of the esophagus will now be considered in more detail.

Pharyngeal Pouch.—By confusion of terms, this condition has often been considered as an esophageal lesion. However, this pouch originates in middle aged persons, at the site of a small gap in the fibers of the inferior constrictor of the pharynx. These patients early note an irritation and an increase of mucus in the throat. As the diverticulum increases in size a characteristic gurgling noise is noted on swallowing. Regurgitation of unaltered food, usually that taken at the beginning of the meal, occurs. In the late stages, the weight of the contents of the sac pulls on the esophagus until it becomes a narrow slit causing increasing dysphagia. The treatment of choice is a two-stage surgical excision of the pouch.

Other Diverticula of the Esophagus.—Traction diverticula occur in the thoracic esophagus as the result of adhesions of inflammatory bronchial nodes dragging on the wall of an esophagus already fixed, producing a tent-like projection of the wall. These diverticula are usually without symptoms and require no treatment.

Congenital diverticula of the esophagus which occur most commonly just above the diaphragm are likewise without symptoms.

Foreign Bodies.—A careful history to determine the character of the foreign body and any previous dysphagia is very important. The dysphagia may be complete or incomplete. Substernal pain with radiation to the back may be present. In many cases in which a foreign body has been swallowed, as for instance a fish bone or a small meat bone, the patient often complains of pain when swallowing for some days

afterwards, but actually has little difficulty in swallowing his food. The mucous membrane has probably been scratched at the time the foreign body was swallowed but this heals quickly. Complicating symptoms of perforation may occur after a foreign body has become lodged in the esophagus.

Congenital Atresia.—In about 80 per cent of the cases of congenital atresia of the esophagus there are associated tracheo-esophageal fistulae.⁹ In this most common type of atresia of the esophagus the upper segment terminates blindly just above the bifurcation of the trachea, while the lower segment has a fistulous communication with the trachea about 0.5 to 1.0 cm. above its bifurcation.

The symptomatology associated with this anomaly is so characteristic that it should be readily recognized. At birth the child appears to be well nourished and usually well developed but has difficulty with large amounts of frothy mucus filling the mouth and pharynx, and drooling from the side of the mouth. When fed, the child eagerly takes the breast and after a few swallows stops, ceases to breathe, becomes cyanotic, and regurgitates frothy mucus and feedings through the nose and mouth. The child appears as if it would drown, but after a period of lifeless relaxation usually recovers and repeats this episode with each subsequent feeding. These infants rapidly lose weight due to starvation and dehydration and often develop an aspiration pneumonia.

The diagnosis is confirmed by passage of a catheter or bougie which meets obstruction 10 to 12 cm. from the alveolar margins, and by x-ray visualization of the blind pouch with lipiodol filling. The presence of air in the stomach in association with atresia of the esophagus is evidence of a fistulous communication with the lung.

The prognosis in these cases has usually been considered hopeless but survival of some of these patients for more than three months following surgery has lent encouragement to this type of treatment.⁶

Acquired and Benign Stricture.—In these cases a history of swallowed caustic or acid, of antecedent trauma to or infection of the esoph-

agus can be elicited. In the case of swallowed caustic there is early pain, salivation, and often complete dysphagia. Then the dysphagia subsides as the edema lessens and swallowing may seem quite normal. In about six weeks the dysphagia increases when cicatricial contraction takes place.

The treatment is gradual dilatation by graduated sounds passed over a swallowed twisted silk thread. Treatment should be persisted in until a size No. 45 French sound is passed, when the caliber of the stricture is large enough to pass solid foods.

Carcinoma of the Esophagus.—About 40 to 50 per cent of all lesions of the esophagus are due to carcinoma^{4,12} and 4 to 5 per cent of all cancer deaths are the result of carcinoma of the esophagus.¹⁰ Ninety per cent are squamous cell carcinomas and are highly malignant.¹³ Men are five times as frequently affected as women.¹² The average duration of the disease is seven to nine months with a history of gradually increasing dysphagia—first to solids, then soft food and later to liquids. Pain may occur early in lesions high in the esophagus but is late in the low lesions and when it occurs there, usually indicates extension beyond the esophagus. The common complications are: involvement of the recurrent laryngeal nerve, causing hoarseness due to vocal cord paralysis; perforation into the trachea or bronchi forming an esophago-tracheal fistula and leading to aspiration pneumonia; and hemorrhage which may be fatal.

In treatment, the best means of palliation is dilatation by means of graduated sounds passed over a swallowed thread as a guide. Gastrotomy, unless done early, carries a high mortality.⁷ Definite relief is obtained in some cases by irradiation but in others the reaction incident to irradiation only seems to add to the discomfort.

In recent years, more frequent successes by surgical extirpation of cancer of the esophagus should make us aware of the value of early diagnosis.³ Esophagoscopy examination has chiefly been used to verify an established diagnosis. For early diagnosis all patients with subjective abnormality in swallowing should be promptly examined with the esophagoscope. Steadily increasing dysphagia in a man past fifty is indicative of cancer of the esophagus.

Cardiospasm.—In cardiospasm there is a diffuse dilatation of the esophagus without anatomic stenosis, a spasm being present at the cardiac end of the esophagus. Dysphagia in these cases is noted with liquids as well as solids, and is especially severe in the case of cold liquids. The obstruction may be intermittent at first, but becomes progressively worse. The patient can often wash food down with water but cannot swallow water alone. Epigastric pain, present in the majority of these cases, often disappears with the onset of dysphagia. This pain may radiate to the back and retrosternally.

Regurgitation at first is immediate on swallowing and later when the esophagus has dilated may be delayed hours or even days. Nocturnal regurgitation is common. This is often accompanied by aspiration of food causing choking and later chronic pulmonary suppuration.

Medical treatment using amyl nitrate or nitroglycerine is sometimes effective in relaxing the cardia. Dilatation of the area of spasm by the Plummer hydrostatic bag is the most effective method of treatment. In cases which fail to respond to all other therapy, cervical sympathectomy has proved of value.²

Perforation of the Esophagus.—A history of previous instrumentation, swallowing of a foreign body, a previous esophageal lesion or an attack of violent vomiting, preceding the perforation, is usually obtained. The patient complains of severe retrosternal or epigastric pain, dyspnea and dysphagia. He appears prostrated, has an elevated temperature, tachycardia and shallow rapid respirations. Emphysema in the neck or over the chest may be noted.

A few of these patients recover without surgical intervention, but the vast majority will die if nothing is done.

Comment.—In most of the cases of dysphagia the diagnosis may be readily made. Careful inspection should reveal any abnormalities in the mouth or pharynx. The hypopharynx and larynx are easily accessible to examination with a laryngeal mirror. In the diagnosis of lesions of the esophagus a careful history will usually indicate a correct diagnosis. The most valuable and

safest method of examination of the esophagus is by the x-ray.

Blind passage of bougies or sounds is to be condemned because of the danger of perforation of the esophagus. However, passage of graduated sounds over a swallowed twisted silk thread as a guide according to the method of Plummer is a safe procedure and most valuable as a diagnostic aid and a method of treatment.

The esophagoscope is an important adjunct in confirming the roentgen diagnosis and in many instances may give more accurate information concerning certain intra-esophageal lesions. For the early diagnosis of carcinoma of the esophagus, any patient with subjective difficulty in swallowing, especially a man over fifty years of age, should be examined by the esophagoscope.

THE TREATMENT OF ATOPIC DERMATITIS*

E. M. RUSTEN, M.D.

Minneapolis, Minnesota

THE treatment of atopic dermatitis is a subject of general medical interest, most particularly to dermatologists, allergists and pediatricians. It involves two considerations: first, treatment directed at the cause, if demonstrable; and, second, symptomatic relief. The former, as far as allergy is concerned, leaves much to be desired. The latter is often inadequate. However, better therapeutic results can be obtained in a greater percentage of patients if both factors are considered in treatment, rather than relying on either one alone.

Allergic Considerations

The enthusiasm for food as the cause of atopic dermatitis is decreasing. It does occur, but the results from diet restriction alone are generally unsatisfactory. The errors, in the past, were due in part to improper evaluation of skin tests and to general enthusiasm because of an occasional startling result. Skin tests, either scratch or intradermal, have, however, a place in the diagnosis of atopic dermatitis if their

limitations are appreciated. They are about 25 per cent accurate in this condition, in all age groups, being more accurate in children and decreasing with age, even though the number of positive skin reactions increases as the individual becomes older. Skin tests with food extracts are difficult to interpret, as well as unreliable. Their value depends upon the experience of the physician.

The direct testing of infants, even when done with utmost care, is difficult to interpret because most irritations produce varying degrees of erythema and urticaria. This same factor is encountered in patients with urticaria and dermographism. Reactions in this group have more clinical significance when obtained by the passive transfer method of Prausnitz and Kustner. Therefore, positive cutaneous tests should serve only as a starting point of elimination management. The benefit derived from omission of an ingested substance can be evaluated in five to seven days. If there is improvement, they should be added to the diet individually to ascertain specific clinical importance. To accomplish this accurately, the physician must have a knowledge of what composite foods contain, so

*Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 31, 1939. From the Division of Dermatology, University of Minnesota, H. E. Michelson, Director, and the Department of Dermatology, General Hospital, Minneapolis, S. E. Sweitzer, Chief.

that the patient can be correctly informed. By so doing, a comparatively short period of time is necessary to establish the status of a number of suspected substances. There should be no prolonged restricted diets of months' duration, without both patient and physician knowing that ingestion of a substance, either qualitatively or quantitatively, causes an aggravation of symptoms. This can be accomplished by instructing the patient to eat specified amounts and as to the interval at which a food may be taken. Often, when several substances have been omitted for a period of weeks or months, repeated ingestions may be necessary to resensitize the patient, as there is a definite relationship between clinical sensitivity and the frequency with which a food appears in the diet. Some patients have an aggravation of eruption by most ingested materials; to avoid all of these for a considerable period of time is more dangerous than their disease. In such cases, some type of non-specific therapy should be tried.

Elimination diets may be used, but they are of value only in detecting ingestant factors. They are in principle a restricted, specified menu of uncommonly used foods. This method of study used by Rowe⁵ and Alvarez¹ is practical in a limited group of patients. They should be observed frequently and regularly, in order that accurate deductions can be made from omission and addition of specified substances. The greatest difficulty encountered is in interpreting cumulative effect, because of limitation of foods permitted.

Substances referred to as inhalants are sometimes called contact reactors, but are in reality multiple positive scratch tests. The substance, air-borne or by contact, is deposited on an excoriated or irritated skin, which causes an exacerbation of symptoms and signs, the degree of which varies directly with the amount and type of reagent and the sensitivity of the individual. The increase of eruption and pruritus in addition to scratching sets up a vicious cycle. This contention is supported by the fact that very few of these substances cause eruptions when applied as patch tests to the unbroken skin. This conception is in accord with the views of Hill,³ who found that when using the environmental allergens which were positive by scratch tests the patient had positive patch tests when

the skin was abraded, but negative when applied to the intact skin. Many of these are common environmental substances, such as house dust, orris root, feathers, silk, sheep wool, goat hair, et cetera. It is also probable that these are oftentimes secondary or irritating factors and if the underlying cause can be successfully avoided they are no longer effective. This may explain in part the improvement which follows hospitalization of patients with atopic dermatitis. Bland ointments, especially pastes and Unna's occlusive dressings, when applied to an eczematized skin, serve as a protective covering against irritating substances.

Inhaled materials can also cause atopic dermatitis and neurodermatitis. Sulzberger and Vaughan,⁶ in experiments on patients with silk hypersensitivity, state: "The most plausible explanation of this phenomenon seems to be that the silk allergin is absorbed in the blood stream (by way of the respiratory tract) of the patient and disseminated to the vascular hypersensitive areas of the skin." Zakon⁷ and Taub have reported atopic dermatitis due to the inhalation of house dust and horse dander. The respiratory tract as a portal of entry is not rare and should be considered in all patients with large skin reactions, especially seasonal and occupational eruptions or those associated with rhinitis, bronchitis or bronchial asthma. When food extracts give large scratch, intradermal or passive transfer reactions, comparable to pollen antigens, they should be considered not only as ingestant factors but also as inhalant causes. Although this is demonstrated most frequently in adults, it should not be neglected as a consideration in the treatment of infants and children.

Treatment by avoidance in this group of patients is not always possible nor practical. The intimate association with dust, feathers and animal epithelials is such that desensitization by subcutaneous injection should be attempted. It should be given a trial in occupational disease, because of the economic factors involved. The results of these treatments, if used in adequate dosage and over a sufficient period of time, are effective in some patients in the alleviation of a portion of their symptoms. Whether the effect of this treatment is specific, has not been satisfactorily explained, as all cases showing clinical improvement do not show a comparable diminu-

tion in the skin test reaction. Generally, however, patients receiving the most benefit show a decrease in intensity of the cutaneous test. Systemic reactions can and do occur following this type of treatment and are most commonly manifested by increase in pruritus, dermatitis, urticaria, rhinitis and bronchial asthma. Therefore, injections should follow dilutions, schedules and precautions as used in pollen desensitization.

Symptomatic Therapy

Palliative treatment is essential in the majority of patients with atopic dermatitis and should be used in conjunction with specific therapy whenever possible. Oftentimes it is the only method which can be used to any advantage. The multiplicity of medications and treatments used by competent observers indicates that none is adequate in all instances. There are, however, certain important factors that appear to benefit the majority of these patients. Among the most important are: changes in environment, non-specific therapy, physiotherapy, and local medication. Change in environment is most easily accomplished by hospitalization where contact factors can be reduced in number, and diet and medication can also be supervised. Most patients have temporary improvement from this procedure. Occasionally change of occupation is necessary. Others gain relief after moving to a warmer climate. Neurocirculatory instability is present in a high percentage of atopic patients, and such cases are helped by physical and mental rest and correction of the underlying instability and exhaustion.²

Various types of non-specific therapy have been used in treatment. Perhaps the simplest is autohemotherapy. This results in some improvement in a few instances. Intravenous typhoid, sodium, thiosulphate, Ekzebral, hyperpyrexia, intramuscular milk, and splenic extract have been tried with varying results. Histamine⁴ has also been used recently. Most of these, if effective, tend to lose their efficacy if given over a period of time and eventually are useless or appear to aggravate the symptoms.

Ultraviolet light, in tonic doses, appears to benefit some patients if used for a considerable period of time. Oftentimes symptoms and eruption are increased, especially if the dosage be

sufficient to produce erythema. Superficial x-ray therapy may be used in older patients if other palliative measures fail, and then only with caution and realization that atopic dermatitis is a chronic recurring disease and that repeated exposures may result in radio-dermatitis, a condition more serious than the atopic dermatitis.

The choice of local medication is based upon the presenting primary and secondary lesions. For purposes of treatment, they can be divided into acute, subacute and chronic. Acute eruptions, manifest by bright erythema, papulovesicles, edema, often respond satisfactorily to astringent wet compresses of lead acetate and alum solution, boric acid or normal saline. This is suitable if lesions are located on the extremities or face. The presence of secondary infections, pustules, and impetiginized areas may be treated with dilute copper and zinc solutions or potassium permanganate. When crusting is localized or extensive, Ung. acid boric or Ung. diachylon can be used for a short period until crusts are removed, following which the treatment is as previously mentioned.

Soothing alkaline antipruritic lotions may be of benefit in extensive eruptions where exudation is not marked, or where packs are unsuitable. Restraints aid in keeping medication in place as well as preventing scratching and excoriation.

Treatment should be continued until there is maceration of vesicles, decrease of edema and erythema. When this occurs, symptoms will decrease and the eruption may be treated as subacute or chronic.

Subacute or chronic stages, present as papules, papulovesicles, dull erythema and lichenification; secondary lesions consist of excoriations, scales and crusts. In these stages the most valuable medication is ointments containing tar, particularly crude coal tar ointments, the percentage varying from one-half to six per cent. Pastes are preferable to greasy ointments. Irritation is not uncommon; however, this can be avoided if a small trial area is used and if weaker dilutions are prescribed. A common occurrence is to have a rapid favorable response, followed by sudden irritation; therefore, the patients should be instructed to discontinue the paste if this occurs. Tar used in hair-bearing areas over long periods is prone to produce folliculitis and

pyodermas. This disappears rapidly on discontinuance of the medication. Multiple keratoses may also appear after prolonged use of tar ointments; they also disappear on cessation of this treatment. Crude coal tar, although very effective, has many disagreeable features, and substitutes may be tried. Bland ointments, such as zinc paste, with 0.5 to 1 per cent phenol or 2 to 10 per cent ichthyol may be used; drying lotions, such as calamine or zinc lotion, with 5 to 10 per cent liquor carbonis detergens, may give desired results.

Greasy ointments with or without medication, and soapy water, tend to aggravate eruptions. A few medications intelligently used, and a knowledge of their indications, contraindications and methods of application, is of utmost importance.

Summary

The best results in the treatment of atopic dermatitis can be obtained by therapy directed

at specific cause and by palliative measures. Skin tests are of value in detecting some causative factors. Local therapy is indicated in most patients and if this is based on presenting clinical signs is a valuable aid in obtaining symptomatic relief.

THE SYMPTOM OF HEADACHE AND SOME CONDITIONS SUGGESTED BY IT*

HENRY W. WOLTMAN, M.D.

Rochester, Minnesota

HEADACHE is a complaint so common that remedies for it are disbursed through slot machines and so vaguely understood that most headaches have been attributed by different writers to disorders of the gastro-intestinal tract, to allergic reactions, to disease of the nose, and most of them, indeed, almost without exception, to the eyes. It is, therefore, deserving of at least passing notice. A further excuse, if one were needed, for dwelling on the subject of headache, is that a few fragments have been added to our knowledge of it.

Often not, headache is a symptom that occurs without signs. It is this situation I should like to discuss. Here all we have to lean upon is the answers to a few questions. These are fragile reeds at best, especially so, if we fail to understand, not what the patient says, but what he thinks he says. Let us ask

him, for example, what he means by headache. It need cause us no surprise when he says that it means a sensation of ants crawling over the scalp. To the question, "Did you never have a headache previous to three months ago?" he may reply, "Oh, yes, I've had headaches all of my life, but they did not trouble me until three months ago." Having just said that they occur only on the right side of the head, he may admit that they sometimes do occur on the left.

Likewise, we should inquire into the frequency, duration and exact location of the headaches; the hour of night or day and the day of the week they may occur; whether they are becoming better or worse; whether there is an aura; what influence a delayed meal, late sleep, worry, fatigue, and use of the eyes have on the headache; whether stooping, jarring or shaking of the head influences the pain; whether cold drafts or local heat affects them; whether there is a family history of headache, hay fever,

*From the Section on Neurology, The Mayo Clinic, Rochester, Minnesota. Read before the meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 31, 1939.

asthma, eczema, urticaria or angioneurotic edema, and whether particular foods precipitate a headache; whether there is evidence of infection or obstruction in the nose or ears; whether the menses or pregnancy influences the headache, and finally what previous treatment was given. Nor must we forget that a patient may have two kinds of headache, the one, perhaps, of little consequence; the other, perhaps, the symptom of a fatal illness.

Let us return to the patient and see what his story suggests.

The Headache of Increased Intracranial Pressure

Perhaps the headache is relatively recent in onset, and is causing more and more discomfort; it is located in the front or in the back of the head, or, if predominantly one-sided, recurs in the same location. Possibly also the headache awakens the patient early in the morning, and may be accentuated or precipitated by coughing, stooping, straining, or shaking the head. There may be associated with it also sudden vomiting, especially before breakfast, and the pulse, if felt carefully for two or three minutes, may be observed to become slow and irregular at times. Such a headache suggests organic intracranial disease, increased intracranial pressure, and this in turn suggests the possibility of tumor of the brain. To be sure, there may be no headache whatever with tumor, even when the intracranial pressure is elevated, and there may be headache with tumor, even when the intracranial pressure is low.¹⁵ Tapping of the ventricles may either relieve the pain or cause it.² The injection of histamine may reproduce the headache, which suggests that, even with tumor, the pain may arise from the arteries.¹⁵

An intense, recurring occipital or frontal headache, of sudden onset and termination, lasting a few minutes to a few hours, which is associated at that time with nystagmus, vertigo, rigidity of the neck, often in extension, less often in flexion, which may be associated with hiccup and slowness and irregularity of the pulse, a headache in which these symptoms are present at the time of the seizure but not during the intervals, suggests an intermittent hydrocephalus, and this in turn a tumor in the ventricular system. Choking of the disks is often absent. Dur-

ing such an attack the patient may look as though he were about to die, and he often does; during the interval he may appear to be in the best of health.

The ingestion of large amounts of fluid or the giving of a standard enema may lead to disastrous results. Spinal puncture, especially in cases of supratentorial tumor, and, according to the usual advice, in cases of infratentorial tumor, is unsafe. The intravenous administration of hypertonic solutions may relieve such a headache but this may be followed later by a severe reaction. The restricted intake of sweetened fruit juices and the instillation of a hypertonic enema may be helpful.

The headaches of sinus thrombosis, meningitis and encephalitis lack well defined characteristics, save that they are often severe and stubborn. More often than not they are attended by signs of disease that at least cause us to flounder among opinions regarding the many possibilities.

Headaches Associated with Decreased Intracranial Pressure

Occasionally an occipital or frontal headache comes on only when the patient is up and about and leaves when the patient lies down. Such a headache is often associated with a low pressure of the spinal fluid. Thus it resembles post-puncture headache. Often it suggests an arteriosclerotic basis, but it may occur in younger persons, who, presumably, are free from arteriosclerosis.

Ruptured Aneurysm

In a young, healthy person who, we may learn, has just been shoveling snow or pushing an automobile, the sudden onset of an excruciating occipital headache or of pain behind one eye suggests a ruptured aneurysm. There is often rigidity of the neck, a slow, irregular pulse, and clouding of consciousness. Also there may be backache, legache and a positive Kernig's sign. Paralysis of the third nerve on one side and hemiplegia on the other are commonly present, since such aneurysms usually occur in the circle of Willis. A spinal puncture discloses free blood.

A similar story but with a lateralized headache and often with less evidence of meningeal irritation, in a person with hypertension, suggests a cerebral hemorrhage.

Hypertensive Headaches

An occipital or frontal headache that may be present on awakening but one that does not awaken the patient, a headache that may wear away as the day progresses, that tends to occur daily, then leaves, and then recurs, suggests a hypertensive headache. The behavior of hypertensive headaches is often confusing. An especially disabling headache seems to result from the combination of migraine with hypertensive headaches. In diffuse arteriolar disease with hypertension, group IV, the pressure of the spinal fluid is commonly elevated and there is usually papilledema, but there is not necessarily headache, and spinal drainage may or may not relieve the headache.

In a noteworthy study of seventeen such cases with necropsy, Rosenberg found destructive cerebral lesions in 71 per cent. These included scattered large and small hemorrhages, infarcts of various sizes and numbers, periarteriolar lymphocytic cuffing, suggestive of an inflammatory reaction, gliosis, and local or general edema of the brain. Conceivably any of these lesions may be related to hypertensive headache. The results of treatment may be discouraging. Reduction in physical and emotional tension through constructive advice, rest, sedation, spinal punctures, and venesection may be helpful.

The passive congestion produced by intrathoracic tumors and the distention of the vessels in polycythemia, may cause distressing and persistent headache.

Arteriosclerotic Headaches

Dull, heavy bregmatic or frontal headaches or occasionally stabbing, sharply localized headaches occur in 44 per cent of patients for whom a clinical diagnosis of cerebrospinal arteriosclerosis is warranted. In this group, 64 per cent of patients have an average blood pressure of 130 mm. of mercury systolic and 78 mm. diastolic.

In a review of 100 cases with a pathologic diagnosis of cerebral arteriosclerosis, three times as many had had hypertension as had a normal blood pressure. About one-third of the patients of each of these groups, eliminating those in whom intense headache symptomatic of a terminal massive hemorrhage into the brain had

occurred, had complained of headache. Obviously this is a field deserving of further study.

Headaches Due to Anomalies or Inflammation of the Arteries

A sharply localizing headache of a duration of months or years induced or accentuated by coughing, stooping or straining, may result from some vascular anomaly, such as the passage of an artery through a canal in the bone. Possibly traction on the anchored vessel may be the cause of the pain.

Inflammation of the extracranial arteries may be painful. Excision of the firm and tender vessel may provide immediate relief. Most carefully studied, perhaps, have been those cases of temporal arteritis.⁹ Inflammation and trauma of the superficial nerves may likewise be the cause of distressing headache. Palpation of the skull is so simple a procedure that it is often neglected. The flashing pains of occipital neuralgia ought to be distinguished from the more persistent pains of neuritis, although local anesthetization as a test and section of the offending nerve may be helpful in either case.

Post-traumatic Headaches

Following injuries to the head, often trivial injuries, there may occur persistent local or general headaches, that are usually accentuated by work of any kind. The features may be drawn and careworn or grim and determined. Often there are a sullen demeanor and complaints of giddiness and loss of memory. Too often, alas, the issue is befogged by concern over compensation payments and the records are littered with the documents of solicitors. All of this would be much less disconcerting to the physician if his knowledge of these complaints were greater. A settlement of the claim does not always cure the patient. Fortunately, encephalograms may reveal cortical damage, which, when it is the only objective evidence available, is helpful, but cortical damage does not always parallel the complaints. The therapeutic benefits of encephalography itself are not so commonly achieved as it was at one time hoped.

It is well to note that a fracture of the skull is usually not found with that more serious complication, chronic subdural hematoma. The accelerating tempo with which mental and motor

signs appear when this is present calls for prompt action if a fatality is to be averted.

Toxic Headaches

The throbbing, frontal headache associated with fever is a good example of so-called toxic headaches. Their relationship to some more obvious cause is usually the reason for classifying them as such.

Headaches Associated with Disorders of the Special Sense Organs

"As very characteristic of eyestrain, we include especially frontal and parietal headaches, or an ache in or around the eyeball itself. But occipital and nuchal pain are frequently symptoms of eyestrain, and, at times, eyestrain leads the patient to complain of pain as low down as between the shoulder blades, which, of course, can hardly be thought of as a headache and yet is closely related to it," says Crisp.

When headaches are related to the ear, the history or signs of infection involving this organ usually lead us to consider this possibility. The retro-orbital pain of petrositis and the pain attending epidural abscess may be of long duration. Such situations challenge our courage, since the treatment involves no halfway measures.

The headaches caused by disorders of the nose, sinuses and nasopharynx incidental to infection, ventilation, contacts and tumors may be intense, but when appropriate treatment is given they often disappear at once.²⁵ Such terms as sphenopalatine neuralgia, great superficial petrosal neuralgia, and vidian neuralgia remain confusing to all but those who know what is meant by "typical."

Rheumatic Headaches

A more or less constant, rather superficial pain, often lasting many months, located over the occipital, nuchal, and upper trapezius regions, which may be tender, a pain that is brought on by exposure to a cold draft or by tension of these muscles, and that is relieved by the local application of heat, suggests a nodular, rheumatic, or fibrositic headache. The eradication of foci of infection, local hot packs and heavy massage are helpful.

Headaches Related to Endocrine Dysfunction

Probably often migrainous in their characteristics, headaches related to endocrine activities require further definition. We shall return to these under the heading of migraine.

A continuous, generalized headache may occur with pituitary tumors, even when these have not broken into the cranial cavity. Radiation of the pituitary region may bring quick relief. Rynearson has treated with at least temporary success such a headache of several years standing, by the weekly administration of 25 mg. of male sex hormone. Similar head pains in acromegaly may depend on the same factors that sometimes cause constant pain in the acral parts of the extremities.

Migraine

Commonest of all headaches, with an incidence twice as high in women as in men,¹¹ and generally picking out the ambitious members of society,^{6,27} with hereditary appearance almost the rule, with a history of recurrence over many years, in which the earliest headaches may have been as severe as any of the later ones; headaches that often appear under stress and at the menstrual period, but that may disappear temporarily during pregnancy, and permanently, but not always, at the climacteric; such headaches suggest migraine. The migrainous attack itself is often introduced by warnings, such as scotomas. The headache itself usually occurs on one side of the head but not always on the same side, or in the same location. Vomiting is not a necessary accompaniment. In 90 per cent of such cases, the headache is relieved by the administration of ergotamine tartrate,¹³ which, incidentally, serves to identify it as migraine.

Much has been learned in recent years concerning the cause of these headaches. The common explanation that the pain results from edema of any part of the brain has not been proved. It is known that the larger vessels of the dura and probably adjacent parts of the dura are sensitive, that the larger arteries at the base of the brain are sensitive, that the venous sinuses are probably sensitive,⁴ and that the tentorium may be. The brain itself and the vessels of the brain and pia are not sensitive.³ It seems remarkable that the seventeenth century Willis¹⁷

could write regarding the headaches of Lady Anne Conway, "Certainly it seems most likely, that the invincible and permanent cause so long and yet not deadly Headache proceeds from such a thing, viz., A Scirrhus Distemper of *Dura mater*, the *Pia mater* being in the mean time safe."¹⁷ Obviously there has been little opportunity to investigate the auras of migraine. It seems likely that constriction of the pial arteries accounts for the scotomas and paresthesias. Loss of appreciation of passive movements has been demonstrated during a paresthetic aura. This indicates that more than the dural vessels take part in the attack³ and suggests that the cortical vessels may go into a state of spasm. Subsequently those vessels dilate.¹⁸

While migraine involves a widespread neurovegetative reaction, of which little is known, the pain itself has been studied carefully. With the help of recording devices Graham and Wolff observed that the height of the headache coincides with an excessive pulsation of the temporal artery. They also observed that the injection of ergotamine tartrate, which stimulates smooth muscle, results, not only in the reduction of the headache, but also in the reduction of the amplitude of pulsations of the temporal artery. Direct inspection of the middle meningeal artery revealed that the injection of ergotamine tartrate caused a constriction of 20 per cent in the caliber of this vessel. The caliber of the sylvian artery or vein, however, was not altered. They observed further that manual compression of the temporal, carotid and occipital arteries caused the pain to subside in the regions supplied by these vessels. Ligation of the temporal artery brought about a reduction of pain at the corresponding site. The residual pain probably arose from within the skull. Following the injection of histamine the pulsations increased again and the pain returned to its former location. Histamine itself does not cause the pain since there was no return of pain until after the injection of histamine had been discontinued;⁴ this means that the systemic blood pressure must return before the impact of the column of blood upon the cerebral vessels is sufficient to cause pain. Thus, it would seem that the pain of migraine results from the stretching of relaxed dural arteries by the shock of arterial pulsation.

The pulsation of the cerebrospinal fluid or its pressure could not be correlated directly with the intensity of the pain, nor were these constantly influenced by the injection of ergotamine tartrate. Other observers, however, have reported that a rise in the pressure of the spinal fluid occurs after the injection of ergotamine tartrate.¹⁹ Any increase in pressure of the spinal fluid would, to be sure, tend to support the vessels.⁴

The injection of ergotamine tartrate also increases the blood flow and the oxygen-carrying capacity of the arteries and veins.¹² Possibly this may be correlated with the recent observations of Alvarez that the inhalation of oxygen may relieve migraine, especially if given early.

These observations seem to explain the relief from pain that occurs in 90 per cent of cases following the administration of ergotamine tartrate.¹³ The early administration of 1 mg. given orally twice daily during an attack of pain, or of 0.5 mg. given subcutaneously, gives strikingly good results.²³ Placed under the tongue ergotamine tartrate is much more effective than when swallowed directly.¹⁶ Some observers give as much as 5 mg. orally in a single dose, and 1 to 2 mg. each hour thereafter until a total dose of 10 to 12 mg. in twelve hours has been given.²⁴ The initial subcutaneous dose is generally 0.25 mg.; not more than 0.5 mg. should be given subcutaneously in twelve hours. Contraindications to the use of ergotamine tartrate are coronary disease, peripheral obliterative disease, acute infections, hepatic and deficiency diseases. Gastro-intestinal symptoms, a sensation of pressure in the breast, pain and paresthesias in the limbs may be relieved by the administration of calcium or of atropine.^{16,24}

As an interval treatment ergotamine tartrate is not recommended. Calcium gluconate and viosterol may be prescribed as prophylactic measures, especially for patients who complain of gastro-intestinal symptoms or allergic phenomena.²⁴ Chondroitinsulfuric acid also may be helpful in this situation.¹⁶

Migraine often disappears during pregnancy, when the follicular hormone is circulating. Some patients respond very well to 5 c.c. of amniotin administered orally in three divided doses per day.²³ Progynon has been recommended, particularly for the pale, round faced, fat women in

whom the onset of menses was late, on whom ovarian operations have been performed, or who are in the climacteric.¹⁶ Emmenin also may be administered.

In the treatment of migraine attention should be given to physical and emotional stresses, refractive errors, gastro-intestinal disorders, allergic disturbances,²² and faulty habits of all kinds. Vacations are often helpful. The administration of $\frac{1}{2}$ grain (0.03 gm.) of phenobarbital three times daily over an extended period of time may be useful.

"Erythromelalgia of the Head"

A unilateral headache, without hereditary incidence or an early history of migraine, a headache of sudden onset and termination, in which the pain tends to awaken the patient at night, which is eased by the erect or sitting posture, which is associated with lacrimation and stuffiness of the nostril, and which is often precipitated by taking alcohol, is suggestive of "erythromelalgia of the head." There are no scotomatous or gastro-intestinal accompaniments. The injection of 0.3 mg. of histamine will produce an attack. Desensitization to histamine by the injection twice daily of 0.05 mg. for two days and subsequently increasing the dose to 0.1 mg. for two or three weeks may result in relieving the patient entirely.⁸

Headaches are said to occur occasionally with gastritis. The insertion of a jejunal catheter for feeding may relieve the headaches. The headaches may recur promptly, however, should the catheter slip, inadvertently, into the stomach, as may be determined by fluoroscopy.¹⁴ Gastric dilatation and atony of the stomach during an attack of migraine have been observed roentgenologically.¹⁰

Psychoneurotic, Psychotic, Neurasthenic and Exhaustive Headaches

A headache that has been present constantly for months on end, one that is often poorly and resentfully described by the patient, is suggestive, not of an organic disease, but of a psychiatric disturbance. The sensation of pulling or drawing in the occipital region, or of a weight on the head, is commonly mentioned by patients who are depressed. In hysteria there may be a striking indifference to the headache when subjects

other than the pain are discussed. It is sometimes, no doubt, a means of escaping responsibility.²⁶ In schizophrenia also the complaint of more or less constant discomfort in the head is not unusual.

When headache is the patient's chief complaint, the causes to be considered are almost without number. A thoughtfully taken history should lead one into paths that call for further investigation. A detailed examination may not be neglected. Nor should a careful inquiry into the emotional state, which so often plays a significant role in the production of headache, be disregarded.

Among the more recent advances in our understanding of this common complaint I should mention three. First, the observations made by Wolff and his colleagues, namely, that in migraine an increased arterial thrust upon the toneless but sensitive dural and extracranial arteries is the cause of the pain, and that the administration of ergotamine tartrate, by restoring tone to these vessels, lessens the violence of the pulsations and thus reduces the pain.

Then I should mention the searching studies made by Rosenberg of so-called malignant hypertension, in which he demonstrated the extent of cerebral damage that is associated with this disease.

Finally, reference should be made to the segregation by Horton, MacLean and Craig, of a type of headache that has certain clinical characteristics and that is amenable to desensitization with histamine, and to which they have given the name, erythromelalgia of the head.

SOME CLINICAL VAGARIES ASSOCIATED WITH BACTERIAL ENDOCARDITIS*

ALFRED HOFF, M.D.

Saint Paul, Minnesota

POSSIBLY only little interest can be aroused by the discussion of a disease such as bacterial endocarditis where therapeutically we are beaten from the start and where the diagnosis appears to be easily made.

The affliction as a rule is readily suspected when the usual criteria of fever, anemia, embolic phenomena and evidence of a damaged heart valve or a congenital heart defect are all present.⁴ When these embolic phenomena are obvious as indicated by petechial hemorrhages in the conjunctiva, fingers or toes, the diagnosis is assured.

However, it is little appreciated that embolic manifestations concealed in deep structures may dominate the clinical picture of this disease and frequently obscure the true nature of the affection. Under these circumstances the correct diagnosis may be missed and only made at necropsy.

During the past few years opportunity has been given me to follow personally with one exception a series of thirteen cases of bacterial endocarditis in which the diagnosis has been conclusively established at the postmortem table. This experience offers rather convincing evidence that we not infrequently fail to make the diagnosis, even under conditions where all diagnostic facilities are available.

It is generally admitted that congenital heart

disease or a previous attack of rheumatic fever predisposes an individual to this affliction.^{4,5,6,7} Usually there have been no recurrent attacks of rheumatic fever and relatively good health has been maintained since the initial infection.⁴ This coincidence has led some writers to the inference that its development is conditioned upon an established immunity to rheumatic fever, because the organisms unable to maintain a continued existence in a highly immune blood stream seek a safe refuge in a platelet thrombus on a damaged heart valve where the blood is unable to penetrate and destroy them.^{4,6,7}

In this series where a positive past history of rheumatic fever was obtained, about eight years of good health preceded the onset of the symptoms of the fatal episode.

The ultimate crippling valve defect of mitral stenosis has been considered the result of a chronic low grade rheumatic infection with recurring episodes of a non-articular character over a considerable period of time.⁷ If so, immunity to rheumatic infection has not been established and upon this foundation one may attempt to explain the relative rarity of mitral stenosis and its associated auricular fibrillation in subacute bacterial endocarditis.

Bell and Clawson believe that rheumatic infection and subacute bacterial endocarditis merely represent different manifestations of the same

*Read before the Ramsey County Medical Society, March 27, 1939.

disease.² However, there is little unanimity of opinion as to just what specific organism is the cause of rheumatic fever. *Streptococcus viridans* is the causative organism in the great majority of cases of subacute bacterial endocarditis.^{1,2,5,6} An infection occurs usually upon a previously damaged heart valve.^{1,2} It is generally conceded, however, that it is possible for some bacteria to focalize and continue to survive upon a previously undamaged valve.⁶

One may be permitted to say that a diagnosis of subacute bacterial endocarditis may be dismissed when no murmur is audible unless other characteristic signs of the disease are present.^{4,5,6,7} A murmur may be absent in a rapidly beating heart.

A transient bacteremia without endocarditis may follow tonsillectomy, extraction of teeth or an upper respiratory infection,³ so that a single finding of this organism in the blood stream, unsupported by signs of a past rheumatic infection in the form of a damaged valve, or a congenital heart defect upon which to thrive, is insufficient evidence to support a diagnosis of the subacute variety.⁶ On the other hand the blood culture may remain negative throughout the course of the disease.^{5,6}

The purpose of this paper is to illustrate with selected cases some of the clinical vagaries as well as to show some of the more common features of this disease.

An effort has been made to chart these cases after the method of Keefer³ under headings which are of diagnostic significance and to briefly summarize the associated necropsy findings as determined by Dr. John F. Noble and his associates at the Ancker hospital.

These cases have been grouped according to the presenting symptoms on admission to the hospital.

Group I. Those with symptoms of progressive congestive heart failure.

Group II. Those with symptoms of pneumonia and meningitis.

Group III. Miscellaneous types.

1. Symptoms of angina pectoris and hemoptysis.
2. Those with neurological manifestations
 - a. Hemianesthesia.
 - b. Meningitis.
 - c. Brain abscess.

3. Symptoms of hyperthyroidism with splenomegaly and anemia.

Group I

Cases of subacute bacterial endocarditis with progressive congestive heart failure (Chart I).

There were five patients in this group, three males and two females. Their ages varied from twenty-three to seventy-eight years.

Three gave a past history of rheumatic fever, ten, eight and thirteen years respectively prior to the onset of the terminal infection. They all gave a good subsequent health record and on admission definite signs of rheumatic heart disease in varying stages of congestive failure were present.

Sustained irregular fever and moderate to severe anemia were present in all. Three showed *streptococcus viridans* in the blood stream. In the remaining two, blood cultures were not made. Early embolic phenomena were seen in two cases.

The duration of recorded symptoms before entry varied from one and one-half years to four months, while the longest stay in the hospital was forty-seven days and the shortest four hours.

All showed traces of albumin and occasional red blood cells in the urine. The pathological diagnosis in all cases was subacute bacterial endocarditis, with the heart valves showing evidence of past rheumatic involvement and superimposed soft friable vegetations involving the aortic and mitral leaflets in two and the mitral alone in three cases.

No instance of diffuse glomerular nephritis was found but embolic involvement of the kidneys was common.

Representative of this group with symptoms referable to progressive congestive heart failure is the following case.

Case 3.—Mrs. V. E. A., aged thirty-eight, was admitted to the hospital December 1, 1938. In 1930, this patient had rheumatic fever characterized by a migratory polyarthritis. She never had symptoms of decompensation following the attack. Four years ago following the onset of a chronic cough, she noted on one occasion a blood-streaked sputum. One and a half years ago the patient developed a progressive weakness and pain and tenderness in her legs. Six months later she noted pleurisy in her right chest which was located under the shoulder blade. June 15, 1938, the patient developed coryza. Since that time she had a productive cough which increased in severity. The sputum was at

BACTERIAL ENDOCARDITIS—HOFF

times blood-streaked. She had recurrent chills and fever and severe night sweats until the time of her admission to the hospital. Three weeks before her admission her legs, ankles, and feet became edematous and she noted some dyspnea on exertion, and palpitation of the heart. The urine was at times coffee-colored and she had some dysuria. She lost ten pounds

faint trace of albumin, occasional casts, a few leukocytes, but no red blood cells were ever found. The hemoglobin was 54-36 per cent; leukocytes, 10,200 and 31,100. The polymorphonuclears were 77-94 per cent with toxic cells seen at one time. The sedimentation rate was 80 mm. per hour. The urea nitrogen, 32.2 milligrams and creatinine 1.8 milligrams.

in weight since June, 1938. Her past history revealed that the patient had chickenpox and diphtheria as a child. Seventeen years ago she contracted syphilis. This was characterized by primary and secondary lesions. She was treated with mercury for a short time. For the past four years she has been treated continuously for syphilis. Her husband died of syphilis. She came in contact with tuberculosis on one occasion.

Physical examination revealed that the patient was underdeveloped and emaciated. She did not appear acutely ill. The blood pressure was 123 over 38, temperature 102.4°, and pulse 100. The skin was pale and moist. The right pupil was larger than the left and neither pupil reacted to light. Examination of the fundi was negative. The breath sounds were found to be decreased on the right and there were a few râles present in the left base of the lung field. The heart was enlarged to the left and there was a rough systolic and a soft prolonged diastolic murmur heard over the entire precordium but most marked at the second left interspace. The heart rate was irregular and numerous extrasystoles were heard. The spleen was not palpable. There was no tenderness nor rigidity in the abdomen. Examination of the extremities showed a slight clubbing of the finger tips. There were ecchymotic areas over the anterior surfaces of both thighs.

Laboratory examinations: The urine contained a

The serum globulin was 1.4 grams; albumin, 3.22 grams, and the sulphanilamide determination on January 6, 1939, was 9.3 milligrams per 100 cc. of blood. Examination of the sputum was negative for tubercle bacilli. Of five blood cultures taken, one was positive for streptococcus viridans. The icteric index was eight and the VandenBergh .1 milligram bilirubin. The blood smears were negative for malaria. The agglutinations were negative. The blood Wassermann was 4+.

The electrocardiogram showed auricular fibrillation, right axis deviation, and ventricular muscle damage. The x-ray examination of the chest showed the heart to equal 60 per cent. There was a generalized enlargement with straightening of its left border and prominence of the conus pulmonalis. There was thickening of the interlobar pleura on the right and increased bronchovesicular markings. Later x-ray showed an increased enlargement of the heart with congestion of both lungs. There was an area of consolidation in the lower portion of the right lung due to pneumonia or infarct.

The patient's clinical course was characterized by cough, night sweats, and occasional chills with a moderately high fever. The temperature ranged from subnormal to 104°. It was mainly irregular but was at times typically septic. The heart continued to fibrillate. Two weeks after admission the patient developed

edema of the legs and râles were heard in the chest. On December 19, 1938, the blood culture was positive for streptococcus viridans. Neoprontosil was then given for two weeks and was followed by prontosil. She was very emotional and at times confused and irritable. Weakness and listlessness were pronounced. She was cyanotic and finally became involuntary. Her temperature terminally was subnormal. No petechiæ were ever found on any portion of the body. The patient expired January 17, 1939.

Necropsy findings—as determined by Dr. John F. Noble:

Diagnosis: (1) Old valve defect (mitral). (2) Old valve defect (aortic). (3) Subacute bacterial endocarditis (mitral, aortic, and left ventricular wall). (4) Thrombosis (purulent) of left auricular appendage and auricle. (5) Bilateral hydrothorax. (6) Ascites. (7) Pericardial effusion. (8) Bilateral atelectasis of the lungs. (9) Thrombosis and infarction of left lung. (10) Passive congestion of lungs-liver-spleen-kidneys. (11) Acute splenitis.

Note: Culture from the septic thrombus of the heart at autopsy shows streptococcus viridans.

Comment. This is a case of subacute bacterial endocarditis occurring in a patient with definite mitral stenosis and auricular fibrillation giving a past history of rheumatic fever eight years previously followed by a relatively good health period, without cardiac failure, until the onset one and one-half year before death of symptoms of recurrent chills, fever and night sweats, terminating seven months after onset in progressive congestive heart failure, auricular fibrillation and marked edema.

This patient failed to respond to sulphanilamide therapy.

Group II

Cases of bacterial endocarditis with acute septic onset with symptoms of pneumonia and meningitis (Chart II).

Not infrequently a patient enters the hospital with symptoms of an acute fulminating infection, suggestive of pneumonia and terminating as a meningitis, or with meningeal symptoms from the start.

Of these there were four patients, three males and one female. One was fifty-one years old, one sixty and two were twenty-four years old.

None of these gave a previous history of rheumatic fever and in only one was a heart murmur heard. The heart was definitely enlarged in two and the rate was rapid in all. The onset was acute, following apparent good health, with

chills, high fever, delirium and signs of meningeal irritation. On admission to the hospital the clinical diagnosis was pneumonia and meningitis.

The temperature was septic and the anemia was not significant. Three presented suggestive embolic signs. The blood culture was negative in one and not made in the others.

The duration of symptoms before entry ranged from two weeks to two days while the stay in the hospital of two patients was twenty-four hours and thirty-six hours and the others nine days and twelve days respectively.

Subacute bacterial endocarditis was found in three cases and the infection was acute in one. The mitral leaflets were involved in two and the aortic in one case. Bronchopneumonia, infarcts and petechial hemorrhages in the brain were seen in the two cases with meningeal symptoms. One patient had a syphilitic aortitis without a syphilitic valvulitis. The aortic leaflet showed a rheumatic deformity with a superimposed bacterial endocarditis.

The case of acute bacterial endocarditis occurred in a woman. The aortic leaflet disclosed evidence of rheumatic involvement and the mitral leaflet a very large, soft, friable vegetation. The uterus was normal in size and its endometrium absolutely smooth.

The following are two illustrative cases.

Case 1. W. S., aged sixty, white, male, admitted to the hospital August 4, 1938. Five days before admission he had become acutely ill with a cough and developed chills, fever and generalized weakness. He was treated by a local physician for a few days. During this period he had coughed mucus but no blood. He did not have any chest pain. His appetite had been poor and he had been constipated during the present illness. Previous to the present complaint he had been well.

Physical examination at the time of admission disclosed an acutely ill, elderly white male whose temperature was 104°, pulse 118, and blood pressure 130 over 70. Examination of the chest revealed the respiratory rate to be 26 with dullness to percussion over the left postero-lateral aspect of the chest. Some bronchial breathing was heard at this site. There were many râles anteriorly in the left chest. Occasional râles were heard in the left base. The heart was rapid; no murmurs were recorded. Examination of the abdomen revealed it to be tympanitic with no palpable masses or tenderness. The liver edge was palpable but not tender. There were a few superficial abrasions about the trunk.

The urine showed albumin, granular casts and a few white and red blood cells. The sputum was negative for pneumococcus. The hemoglobin was 80 per cent

BACTERIAL ENDOCARDITIS—HOFF

and the white blood cells 15,000, of which 89 per cent were polymorphonuclears. The sedimentation rate was 95 millimeters in one hour. The blood urea nitrogen on admission was 60.2 milligrams per cent.

On the following day the patient was lethargic, confused and answered questions with difficulty. There was some neck rigidity. His temperature had increased

atheromatous streaking. The auricular appendages contain no thrombi. The ventricular walls are definitely thicker than normal and there is some dilatation. Microscopic examination of sections of the heart valves shows them to be composed for the most part of connective tissue fibers forming a dense plate."

Head: "Examination of the head shows the sub-

to 104.8. The respiratory rate remained the same and his pulse increased to 130. There was a positive Kernig's sign and the spinal fluid was bloody with 266 cells per cu. mm., 94 per cent being polymorphonuclears. He became progressively worse. The treatment consisted of sulphanilamide. His temperature rose to 106.4° and on the following day he died approximately thirty-six hours after admission.

Notes—Drs. Maun and Dick on the heart and head:

Heart: "The heart weighs 525 grams. The tricuspid, pulmonic, and aortic valves are normal in appearance. Examination of the mitral valve reveals the leaflets to be slightly thicker than normal and somewhat opaque. There is slight contraction in the leaflets. Examination of the leaflet of the mitral valve reveals it to be thickened and in the center of it there is a soft necrotic area which has perforated the valve. This measures approximately one centimeter in diameter. About it, the valve is soft, edematous, and slightly red in color. There are no free vegetations on the margins of the valves. The coronary arteries are normal in appearance. The myocardium is firm and on cut section it is swollen and cloudy in appearance.

"Scattered throughout the ventricle there are small light yellowish areas which do not appear to be connective tissue. There is no gross evidence of excess fat. The root of the aorta shows a mild degree of

aponeurotic surface of the scalp to be ecchymotic over the vertex on the right side and the calvarium shows nothing of note. The surface of the brain shows a number of petechial hemorrhages of varying sizes distributed uniformly over the brain surface. On cut section there are numerous petechiae of varying sizes throughout the gray and white matter involving the falx cerebri, and cerebellum. There are larger areas in the brain substance measuring up to .5 centimeter in diameter. These are essentially in the right parietal lobe, the right occipital lobe, four in the parietal lobe, and several are seen in the white matter of the cerebellum. At approximately the junction of the occipital and parietal lobes in the right cerebral hemisphere is seen an area of softening, which surrounds one of these ecchymotic areas described. There is no other evidence of tumor, hemorrhage or softening."

Diagnosis (Necropsy)—(Drs. Mark Maun and Fred Dick): (1) Subacute bacterial endocarditis. (2) Old valve defect (mitral). (3) Bilateral bronchopneumonia. (4) Infarction of kidneys—brain. (5) Emboli—gastrointestinal tract.

Case 2. H. E.—This patient was a white man aged twenty-four who was admitted to the hospital on August 30, 1939, at 7:44 p.m. He was delirious and in a semi-conscious condition. The history was obtained from his wife. He had been married ten days ago and had

been perfectly well until August 28, when he complained of pain in his stomach after eating. That night his wife was awakened at 12:00 P.M. and found that he did not recognize her. He was delirious and remained so until his admission to the hospital. Two days after onset he coughed considerably and complained of a violent headache. He was very restless. Nausea and vomiting occurred. A doctor was called on August 30 and diagnosed the case as pneumonia.

His tonsils had been removed at a local hospital last fall. His wife said that he had had heart trouble and for that reason was kept in the hospital several weeks after his tonsils were removed. He had been short of breath on exertion and had had palpitation of the heart but never edema of the feet or ankles. He also had had frequent colds and a chronic unproductive cough.

Physical examination showed the pupils to react sluggishly to light. There was a slight discharge from the nose. The chest showed numerous coarse rhonchi throughout. Posteriorly, there was dullness at the right lung base. The heart was enlarged to the left, the apex being in the seventh interspace in the anterior axillary line. There were no murmurs. The rate was rapid. The abdomen was distended. The legs and ankles showed multiple areas of brownish pigmentation. There was marked rigidity of the neck. The Kernig was positive, and the Babinski was positive on the left. The knee jerks were decreased. There was no clonus.

A spinal puncture was done and 20 c.c. of fluid was removed under increased pressure. The cell count was 88. The white blood cells were 14,500. He bled from his nose and mouth. The temperature varied from 102 to 106; the pulse from 100 to 160. He died twenty-four hours after admittance.

Notes—on the heart and brain by Dr. John F. Noble:

Heart: "The heart weighs 361 grams. The tricuspid, pulmonary and aortic leaflets are normal in appearance. The mitral leaflets appear about normal in thickness, and there is no definite evidence of a past infection on inspection. Along its free superior surface of one leaflet there are large, raised, soft, friable, thrombotic lesions. These are continuous over the entire upper surface of the upper valve along the point of contact. The coronary vessels show nothing of note. The myocardium is pale and swollen in appearance, and shows small fatty looking areas. At the tip of the left ventricle, the muscle shows an opaque white spot which appears to be scarring. The root of the aorta shows a mild degree of atheromatous streaking."

Head: "Examination of the brain shows no definite evidence of meningitis save in the parietal lobe of the left hemisphere where there is a small but definite area of infarction, the center of which is yellow. This measures about 5 mm. in diameter. On cut section the brain shows numerous petechial hemorrhages particularly in the white substance, and in some places involves, to a less degree, the cortex. There is no gross evidence of hemorrhage or softening. The cerebral vessels show nothing of note."

Diagnosis (Necropsy)—(Drs. J. F. Noble and C. H. Drenkhahn): (1) Subacute bacterial endocarditis, mi-

tral. (2) Hemorrhagic bronchopneumonia, bilateral. (3) Infarction of the liver, kidneys, spleen and brain. (4) Cloudy swelling of the heart, liver and kidneys.

Briefly summarized we have two patients with subacute endocarditis without demonstrable heart murmurs, possibly because of the rapid heart action, entering the hospital with signs and symptoms of pneumonia and meningitis, who die shortly after admission, one in two days and the other in twenty-four hours, both of whom give a past history of their usual state of apparent good health until the onset of the symptoms initiating the terminal event.

The speed of the fatal developments in these cases suggests that the insidious nature of this disease permits the patient to continue at his daily work for an indeterminate period until a major embolic accident interrupts the even course of the affliction.

As a result the true nature of the condition is unsuspected and the diagnosis comes as a surprise at necropsy.

Group III

This is a miscellaneous group and included three patients whose presenting symptoms also depended upon the early localization of major embolic phenomena.

1. Severe gastro-intestinal symptoms terminating in right hemiplegia.

2. Symptoms of angina pectoris and hemoptysis with sudden and unsuspected death.

3. Sudden onset with right hemianesthesia.

Two of these patients had a previous rheumatic history occurring ten and eight years previously and one an osteomyelitis twenty years before.

Each had enjoyed good health until the onset of his present complaint.

Definite evidence of valvular heart disease, signs of infection and moderate anemia were present in all, while two displayed embolic phenomena. Blood culture was positive in one case. The symptoms at onset were sudden and their character determined by the localization of emboli.

Case 1. P. O. T. complained of abdominal pain, nausea and vomiting and after forty-five days in the hospital he was suddenly seized with severe abdominal pain, became pulseless and died shortly afterwards.

At autopsy, about 1,500 c.c. of fluid blood was found in his peritoneal cavity due to a ruptured mycotic

BACTERIAL ENDOCARDITIS—HOFF

aneurysm of a branch of the mesenteric artery, the cause of which was a subacute bacterial endocarditis.

This patient had three negative blood cultures.

Case 2. R. W. had complained of moderate angina on effort for three months. He continued working until ten days before admission, when he had hemoptysis and

of twenty-four, eight years prior to his admission and developed a stricture which had been dilated three times in the eight-year interval. During this period he had several exacerbations of gonorrhea and also complained of difficulty in micturition.

Examination: The patient was not acutely ill. A blowing systolic murmur was heard at the apex. The

a severe attack of anginal pain which necessitated hospitalization. While apparently in good condition, he suddenly and unexpectedly died, two days after his entry.

At autopsy, "the right main branch of the coronary artery in its distal portion where it supplies the septum between the right and left ventricles shows a definite thrombosis and in the region of the septum near the auricular ventricular sulcus, there is a definite abscess formation and the entire wall of the left ventricle in proximity to the septum shows a large, well-defined yellowish area of infarction. A soft ulcerative thrombotic vegetation is found on the aortic leaflet to be exactly opposite the orifice of the right coronary artery."

The following two cases are of sufficient interest to merit a more detailed history of their symptoms, progress and autopsy findings. They carry a more practical significance than the more common types of the disease just cited and illustrate the value of alertness in recognizing the possibility of multiple embolic manifestations as a causative factor in obscure and uncertain clinical pictures.

Case 3. P. R. F., male, aged thirty-six, last entered the hospital April 8, 1938. His first admission was in July, 1934, when he complained of a severe pain in the sacro-iliac area, making it almost impossible for him to walk. He had acquired gonorrhea at the age

prostate was slightly enlarged and on massage pus could be expressed from the urethra.

The sacro-iliac region was acutely inflamed and a diagnosis of an acute arthritis was made.

The blood, including Wassermann, was normal, the urine negative except for a faint trace of albumin and the sedimentation rate was 78 millimeters per hour.

He left the hospital markedly improved, but he re-entered the hospital five months later (November, 1934) complaining of inability to think clearly, shooting pains in the head, both of four days duration. He said that while driving an automobile he lost control of it and that he had also noted a slight loss of memory for recent events.

The patient showed a delay in his answers and was slow mentally. His memory was poor and he had difficulty naming objects. The blood pressure in the right arm was 76 over 50 and the left arm 134 over 70. There was a weakness of the left facial muscles and a dilated right pupil. A systolic apical murmur was heard. The blood picture was again normal. The urine examination showed a faint trace of albumin. A radiograph of the skull was negative and one of the chest showed the heart to have a 50 per cent cardiothoracic ratio with an increased prominence in the left auricular area.

He left the hospital under protest and was next seen in the out-patient department in 1935, when he com-

plained of photophobia. The fundus examination at this time was negative.

He was readmitted to the hospital in November, 1936, in a stuporous condition. From relatives it was learned that since his last admission in 1935 he had been in an auto accident and had been unconscious for a short period. He remained well for a short time but later began to lose his memory and his condition gradually progressed until he became semi-stuporous.

Examination on this admission revealed his blood pressure, temperature and pulse to be within normal limits. The pupils were dilated, fixed and equal. He gave unintelligent answers to questions. There was a slight rigidity of the neck while the Kernig and Babinski signs were positive bilaterally. The deep reflexes were slightly increased. An apical systolic murmur was again noted. The spinal fluid was cloudy and contained a trace of globulin. There were 495 cells present. The colloidal gold curve was negative. Subsequent examination showed 296 cells with 97 per cent polymorphonuclears. The sedimentation rate was 46 millimeters and the visual field normal. X-ray of the skull showed an irregular mottling in the left frontal area. The tongue deviated slightly to the left and the deep reflexes were increased. He had a left sensory aphasia and was unable to execute orders. The spinal fluid cell count gradually dropped to 16 cells. Occasional slight exacerbations of a low grade constant temperature were present. A diagnosis of a chronic brain abscess in the left temporal area was made.

After six months he had improved markedly and was discharged from the hospital, but four months later was again readmitted with similar complaint. At this time the hemoglobin was 55 per cent, the W. B. C. 7,000 and a normal differential count was present. The urine examination showed a faint to a heavy trace of albumin with an occasional hyaline and granular cast, many leukocytes, and a few erythrocytes. The spinal fluid disclosed a faint trace of globulin, one cell and a typical parietic curve. He was discharged in an unimproved condition.

About six months later on April 8, 1938, he again entered the hospital for the last time. He had fallen out of his bed and was unable to give an intelligent history of previous events.

His blood pressure was 128 over 88, temperature 98.2°, and pulse rate 120. There was a sutured laceration at the left parietal area. The pupils reacted to light and accommodation. The apex beat was palpated two centimeters to the left of the nipple line and a systolic murmur was heard which was transmitted to the axilla. A number of râles were present over the chest. His blood showed a 26 per cent hemoglobin and 1,400,000 erythrocytes and 11,000 leukocytes. He continued to fail rapidly, and expired April 10, 1938, two days after his admission to the hospital.

Necropsy notes by Dr. John F. Noble:

Heart: "The heart weighs 420 grams. The aortic, tricuspid, pulmonic valves are normal in appearance. Examination of the mitral valve reveals a slight thickening of the free margin with a number of soft friable vegetations particularly on the auricular surface. These

vegetations apparently extend from an ante-mortem adherent mural thrombus and this is seen in the left auricle. It is extremely soft in consistency and appears to be recent in origin. The coronary vessels are normal in appearance. The myocardium is somewhat flabby and on cut section is swollen and cloudy in appearance. Near the posterior aspect of the left ventricle there is a large area of fibrosis measuring approximately one centimeter in diameter. Scattered throughout the posterior aspect of the left ventricle there are also several smaller areas of fibrosis. There is no gross evidence of excess fat. The root of the aorta is free from atheromatous streaking. The auricular appendages show no thrombi.

"Microscopic sections of the heart muscle show numerous areas in which the fibers are replaced by connective tissue and fat. These areas are invaded by a small number of chronic inflammatory cells showing evidence that this was probably the site of old inflammation that was probably rheumatic in nature. Sections of the heart and the mural endocardium adjacent to the mitral valve show a similar process with the heart fibers. The endocardium and the portion of the valves shown in this section shows the valves to be markedly thickened and fibrous in nature. This thickening is produced by connective tissue and the presence of a large number of chronic inflammatory cells invading it. Here and there the valves show a few foci of inflammatory cells, which are close to the free margin. This appears to be a more acute process. Along the free margin one can also find round bacteria occurring in strings which are apparently streptococci. The free margin of the valve also shows definite palisading of the inflammatory cells occurring there. These would undoubtedly be histiocytes. This process is to some extent related to the small foci of inflammatory cells. Attached along the margin of the valve one can also see pink-staining homogeneous masses which represent thrombi. The entire process would suggest that the patient had an old rheumatic process producing myocardial damage. It was followed by a long continued rather low grade endocarditis and a terminal acute bacterial endocarditis superimposed upon the latter process."

Head: "On opening the head there is seen to be the previously mentioned laceration in the lateral aspect of the left frontal area. The calvarium shows nothing of note. On opening the dura there is found to be a small amount of adherent blood to the undersurface of the dura in both the anterior, middle and posterior fossa. The blood, however, appears to be recent in origin and can be easily pushed from the dura with the examining finger. There is no evidence of organization in it. Examination of the cerebral surfaces of the hemispheres reveals a deep pit in the left parietal area. On cut section the cut surface of the left cerebral hemisphere shows the frontal lobe to be normal. On cut section through the parietal area there is a large area of softening extending throughout the entire parietal lobe and partially into the occipital lobe. This area lies in the lateral aspect of the lenticular nucleus and in the gray substance of the brain. In its largest area it measures approximately 2 c.c. in diameter. At

one point in the parietal lobe it encroached upon the cortex to produce the deep pits previously mentioned. At the midportion it resembles an abscess cavity but the wall of it is irregular and could be produced by simple infarction. Examination of the right cerebral hemisphere reveals a similar area of softening in the parietal lobe lying lateral to the lenticular nucleus. It is much smaller and measures approximately one centimeter in diameter. It only extends through the distance of several convolutions. Further examination of the brain reveals no evidence of hemorrhage or tumor mass. The middle ears and mastoids are normal in appearance. There is no evidence of skull fracture. Examination of the entire cranial vault shows no evidence of erosion or tumor mass.

"Examination of the brain reveals the meninges to be markedly thicker than normal and they are somewhat hyaline in character. There is a faint trace of fluid beneath the arachnoids. Sections of the brain in the region of the abscesses show them to be infarcted. The entire parenchyma of the brain shows a rather marked degree of gliosis and the areas about the vessels show small collars of round cells. In some sections the vessel walls themselves appear to have thickened. The entire process suggests a chronic inflammation."

Cultures of autopsy:

1. Diphtheroid bacilli in the abscesses of spleen.
2. Hemolytic streptococci in the prostatic abscess and in the brain.

All cultures are negative for gonococci.

Diagnosis: (necropsy)—Drs. J. F. Noble and Mark Maun: (1) Prostatic abscess. (2) Splenic abscess. (3) Bacterial endocarditis. (4) Mural thrombus. (5) Cerebral malacia (bilateral infarction). (6) Infarction of kidneys. (7) Bilateral confluent bronchopneumonia. (8) Old cholecystectomy. (9) Appendectomy. (10) Subdural hemorrhage.

Comment. Here is a patient with a definite systolic heart murmur, signs of infection and severe anemia, who for a period of four years had signs and symptoms of intracranial pathology diagnosed as a primary cerebral abscess, who at autopsy shows conclusive evidence of an old rheumatic valvulitis with a superimposed bacterial endocarditis and multiple infarction of the brain with necrosis.

At the present time evidence exists that all cases of endocarditis lenta do not inevitably die, but that recovery occasionally takes place.⁵ The usual duration before its fatal outcome is considered to be from six months to one year.^{4,6,7}

Many cases are observed in large city hospitals where patients frequently delay entry until absolute necessity makes them seek relief and then death quickly occurs.

Undoubtedly a not inconsiderable number continue at their daily work in an active stage of

the disease, often without medical attention or with an incorrect diagnosis. Some of these may go into a spontaneous remission but after an indeterminate period of time relapse again into an active stage of the disease with fatal results.

The duration of four years in this patient suggests such a possibility.

Case 4. W. J. L., male, white, aged fifty-five, entered the hospital October 10, 1937, died October 28, 1937, eighteen days later. On admission the patient did not give a clear history. He said that he had noted nervousness, a tremor of the hands, weakness, insomnia and palpitation of his heart for a period of about ten years. His physician had considered his condition to be due to a toxic goiter. A subtotal thyroidectomy had been performed in 1935 without apparent relief of symptoms. Another thyroidectomy was done in May, 1937, shortly before admission. This also failed to give him relief. He then received two courses of deep x-ray therapy. The last course was given in September, 1937, shortly before his entry in the hospital. He stated that he had lost 60 pounds in weight during the past ten months. No definite history of rheumatic fever was obtained.

He was an undernourished white male lying restlessly in bed. He was not acutely ill. The blood pressure was 130 over 40. The pulse rate 132 and the temperature 100° on one occasion; otherwise normal during his hospital stay. The left pupil was irregular and smaller than the right. Both reacted to light. The ocular fundi disclosed numerous small hemorrhages throughout. In the left there was a large hemorrhage superior and nasal to the disc. The heart was enlarged to the left on percussion. No thrill was palpated. A soft systolic and diastolic murmur was heard over the aortic area. A positive Duroziez's sign and a Corrigan pulse was elicited. A soft round liver edge and the spleen could be palpated about three inches below the costal margin.

The hemoglobin varied between 36 and 46 per cent and the red blood count was 1,600,000 cells. The leukocyte count was 6,000 and 14,000 cells and differential count was not significant. The blood smears disclosed some anisocytosis and some hyperchromasia. The blood Wassermann was negative but the flocculation was positive on two occasions. The icteric index was five. The basal-metabolic rate was plus 35 per cent. The urine showed a faint trace to a heavy trace of albumin with an occasional hyaline and granular cast and a few leukocytes and red blood cells in all specimens examined. X-ray examination of the abdomen showed enlargement of the spleen and liver. The cardio-thoracic ratio was 53 per cent and there was considerable congestion in both lungs. Throughout his entire hospital course, the patient was somewhat disoriented. He developed moderate pitting edema of the extremities and died on October 28, 1937.

Notes by Dr. J. F. Noble on the heart: "The heart weighs 547 grams. Examination of the aortic valve shows two of the aortic leaflets to be firmly sealed

together, definitely shortened and calcified. Along the free margins of the aortic leaflets there are numerous raised grayish friable vegetations. The mitral leaflet of the aortic valve shows the largest mass of vegetations and this process has completely destroyed the leaflet, undoubtedly causing an insufficient valve. The mitral leaflets appear to have been normal except for an acute process seen on them. Here the vegetations are somewhat smaller but still thrombotic in appearance and friable in consistency. The tricuspid and pulmonary leaflets show nothing of note."

Diagnosis: (necropsy)—Drs. J. F. Noble and Mark Maun: (1) Subacute bacterial endocarditis. (2) Fibrinous pericarditis. (3) Infarction of the myocardium and spleen. (4) Lobar pneumonia (right). (5) Fibrinous pleuritis (right). (6) Old pleural adhesions (right). (7) Cloudy swelling of heart-liver-kidneys. (8) Splenitis. (9) Edema. (10) Congestion of liver.

Comment. A case of subacute bacterial endocarditis with splenomegaly and anemia terminating in congestive heart failure and pneumonia was diagnosed within a year of death as a toxic goiter. One thyroidectomy was performed about a year and the second one four months before his death. He was also given two courses of deep x-ray therapy, the last one immediately before his final admission to the hospital.

Summary

1. This paper is a clinical review, including

necropsy findings in thirteen cases of bacterial endocarditis.

2. These cases have been classified according to their presenting symptoms and signs on admission to the hospital.

3. Embolic manifestations concealed in deep structures may dominate the clinical picture of this disease.

4. As a result one may fail to make the correct diagnosis, which comes as a surprise finding at necropsy.

I wish to acknowledge my indebtedness to Dr. John F. Noble and his associates at the Ancker Hospital for the autopsy records of these patients.

FUNDAMENTAL CONCEPTS OF MEDICAL BIBLIOGRAPHY

THOMAS E. KEYS, M.A.†

Rochester, Minnesota

BACK of an understanding of the fundamental principles of medical bibliography among those who are seriously interested in medicine is regrettable. Too often, medical students are unfamiliar with the literature of medicine, to say nothing of methods of compiling a bibliography on a particular subject. The reason for this ignorance among medical students may be referable to the system of pedagogy employed in many medical schools, a system whose application is not limited to medicine but seems almost to be universal. It is the textbook method of reading. Its weaknesses were pointed out by Dr. Robert Watt⁹ of Glasgow more than 125 years ago. He wrote, "The reading of the student is too often confined to systems and con-

pilations which are generally the work of men of no experience or of men writing under the influence of preconceived opinions. To obtain correct views of medicine, it is necessary to have recourse to original authors, to such as write from actual observation who have seen and treated the diseases they describe."

The textbook system of reading makes small allowance for the student's acquaintanceship with the classic descriptions of disease which might be supplied by courses in medical history and bibliography. Medical bibliography, then, offers a fundamental approach to the study of medicine and its teaching should not be neglected.

Many writers and publishers of medical books and articles are seemingly indifferent to the bibliographic aspects of their work. Among these persons the complaint is often heard: "Bibliog-

†Reference Librarian, The Mayo Clinic, Rochester, Minnesota.

raphy never sold a book," or "This article is merely the result of my own experience," or "Bibliography is a nuisance." Yet, if such a writer or such a publisher would consider the fundamental relationship of bibliography to the proper fulfillment of an author's or publisher's work, perhaps the most serious efforts would be devoted to an understanding of it.

Bibliography is the systematic description of that which has been written; it forms the foundation for new writing. By means of bibliography alone is it possible to reconstruct the work in medicine and surgery of our forbears. Without medical bibliography, the splendid indices of medical literature now available would never have been written, and consequently many important contributions would have been lost. Some time ago, Mr. Frank Place^s suggested that, "The science and art of medicine is so dependent upon its literature that reference to authorities is a recognized part of medical composition. The quantity of such printed matter is very great and quotation of sources is as necessary in medical literature as in any other field of human endeavor."

Search of the literature and compilation of a bibliography have always been considered important steps in the solution of a problem in research. A review of the literature may provide the research student with methods and results which might be applied to the presentation or solution of his own problem. Furthermore, a student contemplating a work of investigation is naturally desirous of knowing what has been written that concerns his subject, so that he may have the benefits of a proper background for his study. It is of importance to him to find out whether or not he is duplicating the work of other investigators in his field.

If he uses the works of others in pursuing his own investigation, it should be a tenet of medical ethics that credit be given to the original writer. If it should happen that a worker actually duplicated the work of another, considerable embarrassment might have been spared him had he known that writers before him had prior claim to a discovery that was new to him. A knowledge of bibliography would seem, therefore, to be an indispensable part of a medical writer's equipment.

To the general practitioner, a most practical reason for acquaintanceship with medical bib-

liography is that such an acquaintanceship provides him with a better understanding of new developments in medical science. New developments are published first of all in the medical journals, and later as monographs or books, but unless the physician as a reader is acquainted with medical indices and their use, rather than the contents of such journals themselves, he will not be able to keep up with the discoveries, because the huge avalanche of literature he would have to read if he did not use indices would bury him.

Recently, Dr. William Bulloch,¹ emeritus professor of bacteriology in the University of London, made an enlightening study which showed the enormity of one aspect of the medical bibliographic problem. From the *World List of Scientific Periodicals*, published in 1934 by the Oxford University Press and containing the names of more than 23,000 periodicals published between 1900 and 1933, Dr. Bulloch estimated 5,000 of such periodicals to be medical. If, accepting Dr. Bulloch's figure of 5,000, it is assumed that the average medical publication is a monthly and that it contains about fifty pages per issue, then in the world's periodical medical literature more than 3,000,000 pages are published annually!

Dr. Bulloch investigated in detail the vast output of literature on various medical subjects. In studying the Index-Catalogue of the Surgeon General's Office (the index to the most complete medical library in the world), he found that about 7,000 articles and books had been published on the subject of syphilis alone up to the year 1893. From 1893 to 1912, 14,000 new articles on that subject were published, and from 1913 to 1932, 21,000 articles on the subject were published. In the course of twenty years, 6,780 articles have been published on cardiac disease; 7,000 on pregnancy, including 116 on the occurrence of quadruplets! Between 1913 and 1932, according to Dr. Bulloch's figures, 1,280 papers were published on the excision of tonsils.

Thus, a knowledge of medical bibliography is an entrée to medical literature. In defense of an important aspect of medical bibliography, namely, the medical library, Dr. Archibald Malloch,⁷ librarian of the New York Academy of Medicine, recently said that physicians should be insured against certain risks which they may encounter after graduation, and he enumerated

these risks as follows: (1) the risk of being satisfied with methods of diagnosis and treatment learned in medical school, (2) the risk of being content with what is good instead of striving for what is better, (3) the risk of intellectual laziness which threatens those in an extensive practice, and (4) the risk of becoming rusty.

For insurance against these dangers, Dr. Malloch suggested: (1) the study of disease among private patients as well as among hospitalized patients; (2) discussions of problems at meetings of medical societies; (3) publication of brief papers about important cases; and (4) the perusal of medical journals and books, so that regular reading becomes a habit.

Before becoming involved in a discussion of bibliographic fundamentals, it seems to me that it might be wise to mention that it is not always necessary that an author give evidence of bibliographic search of the literature. As suggested by Dr. C. V. Weller,¹⁰ the factors which influence the use of bibliography in literary endeavors depend upon: (1) the character of the subject; (2) the degree of familiarity with it which the intended readers possess; and (3) the method of approach employed by other authors. If a well known author is preparing a popular article or a book for the laity, it is assumed that he is well versed in the literature of his subject and external bibliographic evidence would not be of value in such works. Similarly, it is obvious that if an author reviews his own technic as a contribution to the medical literature, it is not necessary for him to append a long list of references to his article.

But the more limited the topic, the more precise its application, the more necessary does it become for the author to give evidence of familiarity with the literature of his subject. In fact, even though the author's thesis may give internal evidence of his acquaintanceship with the literature, it may yet be adjudged as inadequate because of its lack of external evidence when read by the inexpert. Thus, it has come about that a criterion invariably applied to the written presentation is whether or not it is accompanied by an adequate bibliography. Dr. J. F. Fulton⁴ even goes so far as to suggest that the character of the bibliographic citations contained in an original contribution provides an almost unfailing index to the scientific merit of a given work and to the care with which the manuscript as a whole

has been prepared. Carelessly made and inadequate references suggest careless and inadequate thinking. On the other hand, if references are accurate and are in good bibliographic form, it can be assumed that the writer is scientific in his thinking. It is, of course, conceivable that an author may have a perfect bibliography and that his written work may be of no value whatever, although such is not often the case.

One very bad result which accompanies the adjudging of papers by their bibliography is the use of coarse, bulky, undigested and unassimilated bibliography to give volume and dignity to articles altogether unworthy of such appendages.

Another and more regrettable corollary of the aforementioned practice is that there is transmitted by many of these authors the perpetuation of bibliographic error. Errors occur because a careless author generally does not go to the original source for either his reading, a procedure which would seem to be essential, or the compilation of his bibliography. Instead, he trusts that the authors from whom he quotes, without verifying their references, have done this. Hence, careless or hasty bibliographic work often results in the perpetuation of error, misquotation, false translation, and above all, incorrect references.

It is important, therefore, that persons seriously interested in medicine pay attention at least to two fundamentals of medical bibliography, namely, (1) the systematic description of medical writings and (2) the verification of references.

Bibliography is defined in Webster's *New International Dictionary* as: (1) "The history or description of books and manuscripts, with notices of the editions, the dates of printing, et cetera," and as (2) "A list of writings relating to a given subject or author; also a list of an author's or printer's works."

In its earlier meaning, now obsolete, the word bibliography (derived from the Greek, *bibliographia*) referred to the writing of books (*biblia*) and consequently, "bibliographer" was the name given to the writer of books; that is, not the author, but the copyist. In accordance with the newer definition, a bibliographer is a person who writes about books, describing their authorship, printing, publication, and other pertinent bibliographic facts. If bibliography is narrowed down to its commonly accepted meaning, it is thought of as "A list of books of a particular

author, printer, or country, or those dealing with any particular theme; the literature of a subject," the quotation being the fourth meaning of "bibliography" in the Oxford New English Dictionary.*

In its broader sense, bibliography is much more than the art of listing the publications on special subjects. First of all, it is the science of the description of books. Proceeding under such a definition of duties, the bibliographer is concerned with the different methods at his disposal for the description of the physical aspects as well as the subject-matter of books. The science of the description of books also concerns itself with the integration of research. To achieve this desirable end, the bibliographer must have a clear understanding of the relationship of the principles of the classification of books to the use of books. His task, in this capacity, is to bring together related works, and thus have sources on the entire medical literature at his finger tips. In making an analysis of the literature, the bibliographer is performing an indispensable service for medicine.

An important part of bibliography is in its historical aspects. There is no more fascinating subject than the history of the care of the book through the ages. From the papyrus roll of the Egyptians and later the Greeks, the parchment book of the medieval period, the printed book of the middle Fifteenth Century to the well printed and bound volume of modern times may be gathered a great story embodying much of the development of scholarship. The introduction of printing by means of movable types has contributed much to modern concepts of culture, but is only one of the many pleasant topics rewarding study in the realm of bibliography.

An important concept of bibliography is one that has recently been advocated by Dr. John F. Fulton,⁵ Sterling professor of physiology in the Yale University School of Medicine. Dr. Fulton describes his point of view in the following terms: "A modern bibliographer must anatomize his books. He dissects them with infinite patience, lifting their epidermis to find what lies beneath; he is concerned with their joints and ligaments, and has great delight in discovering parts which have been artificially replaced; he seeks for errors in the hand of the maker, but he

reviews with charitable amusement all signs of human frailty. Bibliography is indeed an all-absorbing occupation, but its devotee is frequently face to face with those who fail to understand the source of his enjoyment. A mere list of bibliographical idiosyncrasies with mistaken signatures, pagination and gatherings has little appeal to any not a collector of books; . . . a bibliographer . . . has difficulty in justifying his existence if he fails to make himself useful to those not pursuing his specialized field. He must reveal something more than the mechanics of bookmaking. He can endeavor to assess the importance of a book; he may say how the author came to write it, or investigate the influence which it exerted upon his contemporaries."

Dr. Fulton also believes that the fundamental service of bibliography is the indication of the contents of books, and for this reason he assigns due credit to Albrecht von Haller⁶ as the first bibliographer to take a great step toward the humanization of bibliography. So-called humanized bibliography includes, in addition to the description of books: (1) a brief statement concerning the author; (2) an indication of the contents of the book; (3) significance of the book in history; and (4) a list of references indicating where further information may be found.

It may be well, for a moment, briefly to review the fundamentals of the description of medical writings. A bibliographic description of a book or article includes the following features: (1) the author, (2) the title; (3) the publisher; (4) the date of publication; and (5) the pagination. In special cases, other important but subordinate bibliographic points should be included, such as (A) exact collation, (B) the illustrations, (C) the size of the book, and (D) the special features, such as appended bibliography, personal autographs, association notes and the like. But, for practical purposes, points one to five are sufficient.

1. *The author.*—The author's name identifies the writer of the book or article. The surname should be set down, followed by the author's given names. Example: Alvarez, Walter Clement. It is the practice of some institutions and publishing houses to initial the given names.³ Example: Alvarez, W. C. But if the author has only one given name, it is generally written in full.* Example: Amberg, Samuel. If the author

*A new English dictionary on historical principles . . . ed. by J. A. H. Murray. Oxford, The Clarendon Press, 1888. v. 1, pt. 2. "B", p. 846-847.

*This is the practice of The Mayo Clinic Library.

is a woman, it is necessary to write her Christian name in full in order to distinguish her sex. Example: Flock, Eunice V. If two deceased authors have identical names they may be distinguished by appending their dates of birth and death to their names. Example: Adams, John (1735-1826); Adams, John (1819-1892). Europeans sometimes distinguish identical names by adding to each name the place of the author's residence. Example: Hoffman, Julius (Jena); Hoffman, Julius (Würzburg).

2. *The title*.—The title distinguishes the paper or book from other publications by the same author. It should be copied exactly as it appears on the title page. Words in a title are never abbreviated, but insignificant words may be omitted. Three dots indicate an omission. Example: A treatise on headache and neuralgia . . . with an appendix . . . by David Webster . . . ed. 3. It is customary to capitalize the first word and proper names and adjectives in a title. Other words are written in small letters. If the title is in the German language, all nouns should be capitalized.*

3. *The publisher*.—Another aid in identifying a bibliographic reference is its publisher. In referring to a book, it is customary to include the place of publication as well as the name of the publisher. Example: New York, Macmillan. In case the work is the American edition of an English book, the American place of publication is given. Example: New York, Oxford in lieu of London and New York, Oxford.

For a reference to a journal, the name of the journal is given as the publisher. This name may be in abbreviated form and many bibliographers accept the abbreviations as listed in the Quarterly Cumulative Index Medicus.† A more universal list may be found in A World List of Scientific Periodicals . . . London, Oxford, 1934. In case two journals have identical titles, the place of publication may be added. Example: Archives of Surgery (London) and Archives of Surgery (Chicago).

4. *The date*.—The date establishes the worth of a work as to its timeliness. It is, therefore, a most important bibliographic point. To estab-

lish the date of publication of books, it is proper to write down the copyright date, which is found on the verso of the title page. Often the imprint date (found at the bottom of the title page) is in disagreement with the date of copyright because the imprint date refers only to the year of printing of a particular edition. Misinterpretation of the imprint date has led countless people to believe that they were consulting relatively new books, when in reality the information in the books consulted was actually obsolete and practically worthless.

It is, of course, true, as Dr. Paul White¹¹ has shown, that a late date on a book in no way proves that book to be good. A classic or leading textbook of the past is far more valuable than a second rate volume of the present. But, when a physician is led to believe by the imprint date on the title page of a book that he is reading the latest data concerning, for instance, physiology or pathology, it is almost fraudulent to have him thus gulled by a reprinted copy of an old book. An aid to the identification of the date of a book is the number of the edition in which it is issued, in case the book has been issued in more than one edition. This information should be added after the date of publication. In describing a reference to a journal it seems advisable to include the name of the month or the date of issue, in addition to the year. This information is for the convenience of the reader who makes use of unbound journals.

5. *The pagination*.—In order to differentiate a major opus from a pamphlet, the number of pages should be included in the bibliographic description of a book. If a work is published in more than one volume, however, the number of volumes in the set should be substituted for the pagination. In case the author is citing the work of another to prove a point, the exact page number of the medical work in question should be included in either the text itself or a footnote, but it should not be incorporated in a bibliography. If reference is made to a paper published in a journal, the complete pagination should be given in the bibliography. An additional aid to the identification of an article is the inclusion of the volume number of the journal.

Attention to these points greatly facilitates the usefulness of a bibliography, and utility, it would seem, is the primary reason for the compilation. Moreover, the more bibliographic points that are

*It is common practice among librarians not to capitalize the first letter of nouns in a German title. Such a practice not only has no valid basis, but is actually intrinsically wrong, because the genius of the German language, as well as its philological aspects, demands that nouns have capitalized initial letters.

†Included in Morris Fishbein's book (op. cit.).

added, the more the possibility of error is reduced. That is, if the volume number is incorrectly given, chances are that the year or the pagination will serve to help locate a "lost" article.

Examples: Correct reference to a book: Willis, H. S.: Laboratory diagnosis and experimental methods in tuberculosis. Baltimore, Thomas, 1928. 330 p.

Correct reference to a journal article: Wilder, R. M.: Hyperparathyroidism: tumor of the parathyroid gland associated with osteitis fibrosa. *Endocrinology*. 13:231-244 (May) 1930.

Correct reference to a chapter in a book by several authors: Allchin, W. H.: Tuberculosis of the peritoneum. In: Allbutt, T. C., and Rolleston, H. D., eds.: *System of Medicine*. London, Macmillan, 1908, vol. 3, pp. 957-978.

The author in preparing his bibliography for publication should, of course, remember to pattern his references after the custom of the publisher who is to publish his work. That is, a paper submitted to the *Journal of the American Medical Association* should follow the rules of citation of that publication, and a paper submitted to the *American Journal of Physiology* should conform in its bibliography to the form used by that journal. The form employed can be easily determined by consulting the particular journal. Another point might be emphasized: The author should be consistent in citing references. He should learn to make them correctly, adhering to this procedure until accuracy and care become habitual, so that reference work eventually will not be any trouble to him, to his readers or to his publishers.

After the author has compiled his bibliography and has prepared his article for publication, his task is still incomplete until he has verified his references. Verification would be a waste of time if all writers were 100 per cent accurate in citing their sources. But the possibilities for error in bibliographic work are endless. How often are mistakes made in copying the volume number, the page number, the year, the author's name, and even the title of a publication!

There is much in the literature on the subject of the perpetuation of errors in medical bibliography. A recent article by Dr. Clifford Dobell² traces the birth and death of Dr. O. Uplavici (1887-1938), who turned out to be a wholly fictitious personage. According to Dr. Dobell, "Dr.

Uplavici, though a pure Czech, had a Greek father and a German mother. He was born in 1887, published his only paper in the same year, obtained his doctor's degree later in the United States, and now—after a checkered career in many countries—breathes his last . . ." After much search in the literature, Dr. Dobell found Dr. Jaroslav Hlava (1885-1924), a distinguished Czech physician, to be the author of an article on amebic dysentery which for fifty years had been falsely attributed to a Dr. Uplavici. The error was perpetuated because Dr. Hlava's original paper had been published in *Časopis lékařů českých* (Journal of the Czech Physicians) of Prague in v. 26, No. 5, for Jan. 29, 1887. Hlava's paper was written wholly in the Czech language and was entitled, "O úplavici Předběžné sdělení" (On dysentery: preliminary communication). Because no translation of the paper in any language had been published, the original is still known to most workers by a brief abstract of it which was published in German in the *Centralblatt für Bacteriologie und Parasitenkunde*, v. 1, p. 537; 1887. But by some extraordinary mistake, the author's name was entirely omitted from the German abstract, and the title of his paper, "O úplavici" was given as Uplavici, O., so that it appeared to be the author's name.

In this strange manner, a new worker, O. Uplavici of Prague, made his first appearance in the literature on amebic dysentery. This particular confusion of title with name led to much confusion in the literature, and Hlava's name has been incorrectly referred to as O. Hlava (instead of J. Hlava) and also as Hlava, Uplavici, and O. Uplavici. Dr. Dobell adds that in a recent paper both Hlava and Uplavici were mentioned as two different workers who studied dysentery among cats in the early days.

Many other examples of the perpetuation of error in medical bibliography might be given, but the aforementioned instance should suffice to make the reader realize the necessity for verification of all references. It is most important that an author take the trouble to verify a statement he is quoting from another, for the writer from whom he quotes may himself be quoting another author inaccurately. If the original source is unobtainable, mention should be made of the writer from whom it was obtained. The author should not only verify the bibliography in his manuscript, but he should also verify it in the

printed proofs of his paper, for more errors may have crept in since his original manuscript left his hands.

To do a perfect job of verification, the original books and articles should be compared with the bibliography and all bibliographic points should be proved. Verification should not be done from the indices to the medical literature except on those rare occasions when an author has read the original reference elsewhere, not in his own local library. If he has used a secondary source, then mere literary honesty demands that he quote that source.

To borrow a conclusion from Mr. Frank Place because it cannot be stated any better: "Take no reference for granted. Verify the reference that your best friend gives you. Verify the reference that your revered chief gives you. Verify, most of all, the reference that you yourself found and

jotted down. To err is human, to verify is necessary."

CYSTOGRAPHY IN THE STUDY OF DIFFICULTIES FOLLOWING PROSTATIC SURGERY*

THEODORE H. SWEETSER, M.D.

Minneapolis, Minnesota

I HAVE previously¹ discussed the principle that the preoperative diagnosis of vesical neck obstruction should be made as completely and accurately as possible with the least possible disturbance to the patient. I maintained that cystography has much value in such a program, a concept well recognized in the literature but apparently not widely followed in practice. If such a principle applies to the primary study of vesical neck obstruction, how much more should it be applicable to the study of difficulties following operations on the prostate and vesical neck. Such a study demands not only thoroughness and a clear demonstration of the condition present, but also tact, diplomacy and usually some regard for the expense of the proceedings.

A fairly extensive literature regarding cystography and urethrocystography has grown up in the last twenty years, but this valuable means of diagnostic study seems still to be neglected. Several prominent urologists have told me that

they do not use cystography nearly as much as they should, and one or two recently have asked what I could determine from cystography that I could not determine from cystoscopy, especially with the retrospective telescope.

Cystoscopy, including inspection of the bladder neck with the right angle and retrospective lenses and inspection of the prostatic urethra by direct and oblique vision, has long been the standard method of study. But I think you and the men with personal experience will agree that cystoscopy should be the last rather than the first preliminary examination, especially in old and feeble men. Cystoscopy is sometimes technically difficult or impossible in these patients previously operated upon because of distortion or stricture of the urethra, and it sometimes fails to give complete or accurate information because of bizarre irregularities.

Urethrocystography has been used with skill and excellent results in certain clinics in this country and abroad. Without question it can be made to furnish a more complete picture than cystography but requires more skill and

*Presented before the meeting of the Western Surgical Association at Omaha, Nebraska, December 2, 1938.

experience in production and interpretation, and therefore is not apt to become as practical for the man of less than large urologic practice.

Excretory urography may be made to give

more clearly than cystoscopy, especially when interpreted in conjunction with rectal examinations, and it gives a graphic permanent record of the findings for later comparisons. Although it

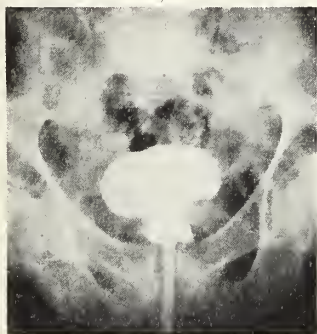

Fig. 1. This patient, about eight months after suprapubic prostatectomy, complained of frequent urination without any residual urine after voiding. The cystogram shows a small rigid bladder and a rigid irregular non-collapsing prostatic space.

Fig. 2. This patient had vesical and prostatic calculi and hypertrophy of prostate when suprapubic prostatectomy was performed in 1923; he has had many stones removed by cystoscopic means since. One can see the shadows of calculi in the prostatic space, and the thin layer of tissue between them and the bladder cavity.

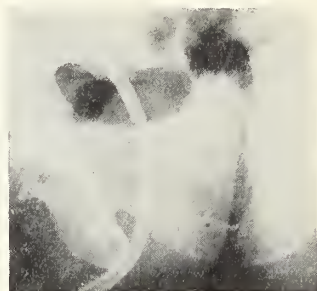

Fig. 3. This patient had a suprapubic prostatectomy sixteen years ago. This recent cystogram showed a typical benign prostatic hypertrophy, and 40 grams of tissue were removed by suprapubic prostatectomy.

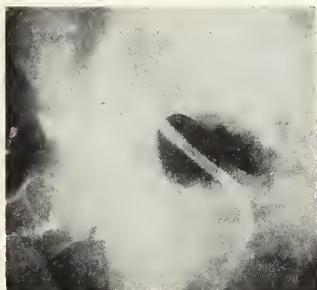

Fig. 4. This patient had a suprapubic prostatectomy seventeen and one-half years ago and a transurethral prostatic resection three and one-half years ago, with removal of 20 to 25 grams of tissue. At the time of this cystogram the residual urine still measured 375 c.c. Further resection of 27 grams gave a completely satisfactory result. The irregular projections into the bladder base indicate a combination of adenomas and scar tissue.

Fig. 5. This patient, at the time of cystography several months after transurethral resection, was having difficulty in voiding; he later underwent another operation. There is a slightly convex elevation of the bladder base around the urethra with the normal curve of the bladder base farther to the side.

Fig. 6. This patient underwent transurethral prostatic resection, after which he emptied his bladder completely but had persistently frequent and difficult urination. The cystogram showed a large, though faintly seen, mass projecting into the bladder anterior to the catheter; the trickle of fluid down the urethra far anterior to the catheter further demonstrates the size of the lateral lobe enlargement. By suprapubic enucleation I removed a large mass of tissue consisting of the anterior part of one lateral lobe of the prostate.

good cystograms if the renal excretion is satisfactory, but it is not always definite and is relatively expensive.

Cystography is a simpler procedure than urethrocytography and is less disturbing to the patient than cystoscopy. Excellent cystograms have been made by several of my friends in general practice. Cystography may show the status of the bladder and bladder outlet even

may not be accepted as advisable for routine follow-up after a primary operation, especially when there are no signs of trouble, still cystography is a simple and safe means of checking the result.

Certain errors in technic and interpretation are possible but such may be said of any method of examination. I have several times wished that I had made a preliminary cystogram,

especially the oblique view, before undertaking cystoscopy. This has been true in cases studied after previous operative treatment even more than in cases with no such previous history.

amount of tissue suprapubically or by transurethral resection (Fig. 3).

After transurethral prostatic resection, complete or partial failure to empty the bladder is

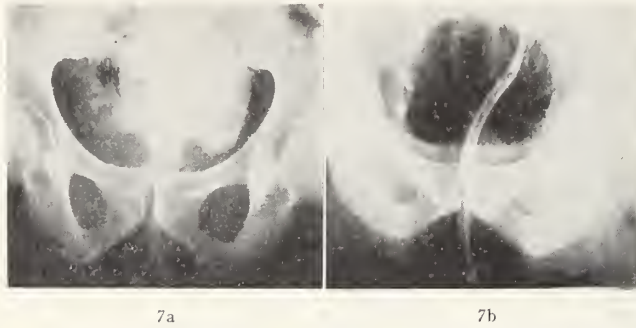

Fig. 7. This patient had two transurethral prostatic resections about one week apart and was having a rather stormy convalescence two weeks later when the cystogram (a) was made. It showed incomplete filling of one side of the bladder and also the remaining intravesical prostatic tissue and the fair channel where tissue was resected. Eight months later the cystogram (b) showed complete rounding out of the bladder outline but still some persistent prostatic shadow. The patient is now so well and so well satisfied with his present condition that he has not availed himself of my offer for another cystogram.

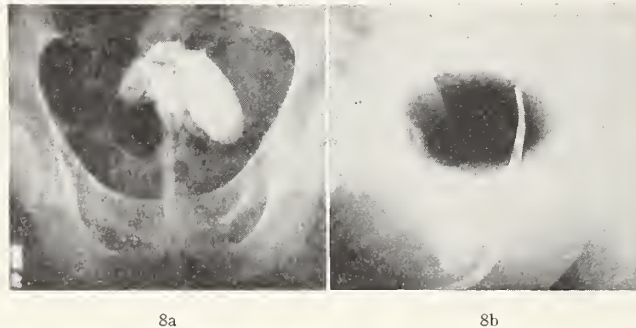

Fig. 8. This patient had a cystotomy followed by transurethral prostatic resection elsewhere in April, 1935. In August, 1937, he was again having trouble. Flat radiograph of the pelvis (a) showed calculi of such size and number that I removed them and some remaining prostatic tissue suprapubically. He has been very well since; a cystogram (b) in November, 1938, showed a satisfactory bladder outlet and no calculi.

Prostatic obstruction being removable by transurethral resection or by enucleation suprapubically or perineally, difficulties may follow any of the methods. My experience with the perineal operation is too limited to mention.

After suprapubic prostatectomy, continuing infection occasionally results in persistence of a large, rigid, infected prostatic space and an irritable bladder of small capacity (Fig. 1). Sometimes this rigid space contains calculi and may be separated from the bladder partially by a shelf of scar tissue and internal sphincter muscle (Fig. 2). Several times I have seen recurrence of obstruction fifteen or twenty years after prostatectomy, and have removed a fairly large

due to incomplete removal of prostatic tissue projecting into the bladder or into the urethra (Figs. 4, 5). If remaining tissue is situated anteriorly in the lateral lobes or in the anterior lobe, the difficulty may be recurring hematuria or dysuria and bladder irritability without failure to empty the bladder (Fig. 6). In one case during a stormy convalescence we found evidence of damage or inflammatory reaction of the bladder wall in addition to incomplete removal of the prostate (Fig. 7). Occasionally the hematuria and irritability are due to calculi, associated with some remains of the prostatic obstruction (Fig. 8a). After one has given appropriate treatment of the patient's difficulty,

cystography (Fig. 8b) is a simple and safe means of rechecking the adequacy of the treatment. Occasionally the source of difficulty some time after a prostatic resection is some other

caution, it should be available at least as a preliminary means of study to those not equipped to do cystoscopy. Cystography may be done as a step in excretion urography, or separately by

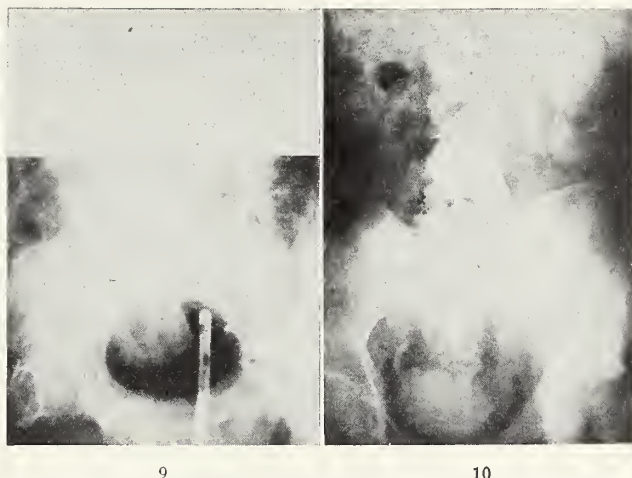

Fig. 9. This patient underwent suprapubic cystotomy and cauterization of a bladder carcinoma elsewhere in June, 1937. Prostatic resection was done in November, 1937, because of a persistent suprapubic sinus. This cystogram of April, 1938, shows no vesical neck obstruction and no trouble in the scar of the previous cauterization (to right of catheter tip on radiograph). Note large tumor projecting into the bladder from its vault (to left of catheter tip on radiograph).

Fig. 10. This patient had prostatic resection in California two years ago. Two months ago, also elsewhere, he had two resections (18 grams and 7 grams). Urography shows no vesical neck obstruction, but evidence of left hydronephrosis and a very marked osteoblastic involvement of the left side of the pelvis and lumbar spine evidently originating from carcinoma of the prostate.

lesion, such as carcinoma of the bladder (Fig. 9) or metastases from carcinoma of the prostate (Fig. 10).

In conclusion, I wish to offer cystography as a simple and safe means of investigation of difficulties following prostatic surgery. With

catheter injection of air or radiopaque fluid. In my opinion it should usually be used in such cases before deciding on cystoscopy.

BALANCING THE HEALTH BUDGET

Testimony before the Sub-committee of the Committee on Education and Labor of the United States Senate, by Dr. Thomas Parran, Surgeon General of the United States Public Health Service: "In connection with balancing the budget, Mr. Chairman, I hope that this Congress will give more attention to balancing our health budget. It is cheaper to keep a woman from dying in childbirth than to take care of the orphans in an orphan asylum or to give aid to the dependent children. It is cheaper to aid in building tuberculosis sanatoria than it is to pay for the deaths from tuberculosis and the widows and children who are left. The State Health Officer of Tennessee estimates that it costs on the average of \$150 to bury a person in Tennessee, and on that basis it is costing that State more to bury people dying from tuberculosis than expense for its entire health program including tuberculosis and all the other diseases."

CASE REPORT

PERFORATION OF MECKEL'S DIVERTICULUM BY FISH BONE*

Report of Case

R. V. WILLIAMS, M.D.

Rushford, Minnesota

MECKEL'S diverticulum was first described by Johann F. Meckel in 1809 and 1812 and according to Gray's Anatomy it is described as follows:

"Meckel's diverticulum consists of a pouch which projects from the lower part of the ileum in about 2 per cent of subjects. Its average position is about one meter above the ileocolic valve, and its average length about five centimeters. Its calibre is generally similar to that of the ileum and its blind extremity may be free or may be connected with the abdominal wall or with some other portion of the intestine by a fibrous band. It represents the remains of the proximal part of the vitelline duct, the duct of communication between the yolk sac and the primitive digestive tube in early fetal life."

Roy Shannon in the *Archives of Pediatrics*, December, 1928, said:

"According to Fitz, in the newborn it lies about 12 inches above the ileocecal valve, while in the adult this is increased to about three feet. The diverticulum may be long or it may be short, or may or may not have a separate mesentery; or may be contained within the mesentery of the small bowel. It may be fixed at its distal extremity to the umbilicus or to any structure within the abdominal cavity. It is often conical in shape with the base large, even approaching in size the diameter of the small bowel at this point. According to Christopher, it usually has the same coats as the intestine, the mucous coat containing Lieberkuhn's glands and Peyer's patches. This same writer quotes Aschoff as saying that it may contain gastric glands, ciliated epithelium and even pancreatic anlage. A certain number of Meckel's diverticula are associated with deformity of the umbilicus, and marked retraction of the naval therefore always brings to mind this possibility."

The incidence of Meckel's diverticulum, according to the literature on this subject, has changed considerably in the past forty years. The earlier authors quoted the incidence as 1 per cent, while the literature written the last five years, which has been quite extensive, quotes the incidence as 2 and 3 per cent. This change, I think, can be fairly stated as due to the fact that the surgeon has become more and more diverticulum minded. Meckel's diverticulum is apparently found more often in males than in females, the ratio being about 2:1.

Case History

The patient, male, sixty-two years old, was born in Fillmore County, Minnesota, of Norwegian parents and for the last twenty-six years has been a rural mail carrier.

*Read before the meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 18, 1939.

Previous history.—At the age of fourteen years, or in 1891, the patient was taken rather suddenly with severe "abdominal cramps" as he remembers the symptoms and also with vomiting. The nearest doctor was sent for, but he was twelve miles away and twelve hours elapsed before he could get there. By this time the symptoms were pretty well over. He was left with considerable soreness over the right side of the lower part of the abdomen which he remembers very well to this day. At the age of nineteen years he had pleuropneumonia which was followed by an empyema. He was operated on at a La Crosse, Wisconsin, hospital. He was in the hospital for five weeks and recovered fully. Since this date, 1896, he never suffered any illness of importance, but in his own language had had a day or two with a severe "bellyache" which came on at intervals of from two to five or six years without any particular reason and always centered in the right lower quadrant. He never passed any blood to his knowledge but sometimes he would have some bowel disturbance, and there was always some tenderness which lasted for a day or longer.

Present history.—About three days previous to April 28, the date I was called, the patient began having an attack similar to those described previously and differing only in that there was no let-up and every day the pain was just a little bit worse. He kept right on making his usual rural mail route trips and in the afternoons would busy himself preparing an acre of tobacco ground. During the afternoon of the third day of this attack he pitched fertilizer. About 5 o'clock he got some very sharp stinging pains and reached home with considerable difficulty. He was nauseated but did not vomit. I was called about 7 o'clock in the evening.

Examination.—The patient was a large robust man, 5 feet 11 inches tall, and his weight was 190 pounds, which had been his usual weight for many years. His temperature was 101.4° F. and the pulse 96. Heart and lungs were normal. The abdomen was slightly distended. There was a great deal of tenderness over the entire abdomen and a marked amount of rigidity. This tenderness and rigidity were much more evident over the right lower quadrant. Every few minutes he would say, "There comes another of those terrible sharp pains," and the abdomen would become very rigid. The urine was negative and the blood count showed over 16,000 leukocytes.

An extensive peritonitis was quite evident, probably due to a ruptured appendix, and an immediate operation was advised. The patient was taken to a La Crosse, Wisconsin, hospital and was operated on about 10:30 p. m.

Operation.—A split muscle opening was made and a large amount of dark watery fluid presented itself first. The appendix was easily found and showed no signs of either present or former inflammation. Upon investigation it was found that the seat of the trouble was toward the median line and could not be reached

(Continued on Page 66)

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF MEDICINE IN HENNEPIN COUNTY

BY A. S. HAMILTON, M.D.

(Continued from December issue)

The directories for 1867 give the list of physicians in Minneapolis and Saint Anthony as follows:

Minneapolis

Ames, A. E. and A. A.
Butler, L.
Bowen, J. S.
Elliot, A. F.
Elliot, J. S.
Evans, O. J.
Hatch, P. L.
Hill, N. B., and Lindley, A. H.

Huntington, T. R.
Leonard, W. H.
Linn, J. J.
Ortman, A.
Shippen, Edward
Snell, E.
Weisel, W.
Wheat, J. N.

Saint Anthony

Dibb, Wm. D.
Jewell, Geo. P.
Jewell, L. P.
Johnson, A. E.
McKay, John
Stockton, E. A.
Stockton, E. H.
Rankin, S. F.

Daily Tribune, November 28, 1868:

"At a meeting of the Union Medical Society held last evening at the office of Drs. Hill and Lindley the following named officers were chosen for the year: President, A. E. Ames; Secretary, N. B. Hill; Librarian, A. H. Lindley. The Society is at present composed of the following named members: Drs. A. E. Ames, G. H. Keith, W. D. Dibb, A. Ortman, N. B. Hill, O. J. Evans, W. F. Hutchinson, J. J. Linn, C. A. McCollom, H. A. DuBois, C. G. Goodrich, H. H. Kimball, C. J. DuBois. The next regular meeting will be held on the first Saturday in December at the office of Dr. W. F. Hutchinson."

Some time in the course of this year, during Dr. Ames' absence in California, Dr. N. B. Hill was made president of the society, but I could find no record of the occasion in the daily papers.

Daily Tribune, Dec. 4, 1868:

"At a meeting of the Union Medical Society last Tuesday it was unanimously agreed that in future all bills should be presented for payment within sixty days after the termination of treatment of a case. Mr. J. C. Hall has been chosen collector for the Society."

Daily Tribune, March 20, 1869:

"The regular meeting of the Union Medical Society will be held this evening at the office of Dr. W. F. Hutchinson in Centre Block."

No account of the April meeting has been found.

Daily Tribune, May 16, 1869:

"At the annual meeting of the Hennepin County Medical Society the following officers were chosen for the following year: President, A. E. Ames; Vice President, N. B. Hill; Secretary, W. F. Hutchinson; Librarian, O. J. Evans. The following committees were appointed: Ethics—Goodrich, Linn, Ortman. Publications—Lindley, McCollom, Kimball. A special committee was also appointed to assist the Health Officer in the discharge of his duties."

Evidently the change in name of the society occurred between March 20, 1869 and May 16, 1869.

Daily Tribune, June 12, 1869:

"A special meeting of Hennepin County Medical Society to be held this evening at the office of Dr. Hutchinson. All members are requested to be present. W. F. Hutchinson, Secretary."

Daily Tribune, Sept. 18, 1869:

"In September, 1869, Minneapolis was visited by Sir Henry Holland, the eminent English physician [eminent he certainly was if his experience was as extensive as is indicated in the notes that follow in the *Tribune*]. He was consulted in Napoleon's last illness, attended Mrs. Thrale (Dr. Johnson's friend), was the physician and friend of the poets, Campbell, Moore and Rogers, as well as of Madame D'Arblay, Joanna Baille, Lord Brougham, Sydney Smith, Macaulay and others. He was present at the deathbed of Channing and knew Madame de Staël, Talleyrand, Byron and Sir Philip Francis."

Daily Tribune, June 8, 1870:

"Hennepin County Medical Society held its annual meeting yesterday. It was chiefly a business meeting. A new constitution and by-laws was adopted, modeled after that of the State Society. The election of officers for the ensuing year resulted as follows: President, A. E. Ames; Vice President, N. B. Hill; Secretary, Geo. H. Keith; Treasurer, O. J. Evans. The president appointed the following standing committees: Ethics—C. G. Goodrich, A. H. Lindley, J. J. Linn. Membership—M. D. Stoneman, W. G. Hutchinson, H. H. Kimball. Dr. Kimball was appointed to prepare and read an essay at the next regular meeting."

This is the first reference I have found in the papers to any program, though, according to Dr. Phillips, it was by no means the first paper.

Daily Tribune, Aug. 2, 1870 (Tuesday):

"Regular meeting this afternoon at two o'clock at the office of Drs. Hill and Lindley."

It was evidently at this meeting that Dr. Ames presented the paper referred to at the beginning of this chapter. According to his statement the society had enrolled up to that date thirty-nine members, of whom four had died and seventeen had moved away, leaving eighteen members at that time in the society. The four who died were the following:

Dr. C. W. LeBoutillier, who was a graduate of the University of Paris, came to St. Anthony in 1854, and died in 1863. He is referred to elsewhere in this article.

Dr. E. Denny Olds, who was made a member of the Society on December 17, 1855, later left Minneapolis, and went to Mexico, where he was assassinated in 1858.

Dr. F. C. Lowenburg, who was a graduate of Leipsig University, came to St. Anthony in 1855, and died in 1864.

Dr. J. White, who was a graduate of the Medical College of Brunswick, Maine, came to St. Anthony in 1853, and died in 1856 at thirty-three years of age.

The list of those who had moved away is as follows, and is specially interesting as showing how widely distributed these former members of the society had already become in 1870:

Dr. John H. Murphy came to Saint Anthony in 1849. After the close of the war he took up his residence in Saint Paul, where he still resided.

Dr. J. W. Wheelock had moved to and then resided in Clearwater, Minnesota.

Dr. Charles L. Anderson came to the city in 1853, and in 1861 moved to Carson City, Nevada, where he remained two or three years. In 1870 he was residing in Santa Cruz, California.

Dr. J. Wilkin had remained in Minneapolis but a short time, and his address in 1870 was unknown.

Dr. W. H. Gould lived for many years in Saint Anthony and practiced dentistry. In 1870 he resided in Boston, Massachusetts.

Dr. M. R. Greely came to Minneapolis in 1857, and was at this time residing in South Weymouth, Massachusetts. During the Civil War he served as assistant surgeon to the 3rd Minnesota Regiment of Infantry.

Dr. D. C. Ayres remained about two years. His address in 1870 was not given.

Dr. Henry Gilbert remained in Minneapolis about one year, and in 1870 was living in Brooklyn, N. Y.

Dr. R. H. Ward was in Minneapolis but a short time, and devoted his attention to microscopy. He was then residing in Troy, New York.

Dr. Albert A. Ames was a graduate of Rush Medical College and practiced medicine in the city about three years, and was later surgeon in the Seventh Regiment. He left for California in 1868, and in 1870 was living in Portland and was editor of the *Portland Daily Bulletin*.

Dr. A. Judson Grey was in the cities one year, and in 1870 was residing in Providence, R. I.

Dr. J. J. Bowen was living at La Grange, Indiana.

Dr. H. A. DuBois was an active member of the society about one year. In 1870 he was practicing in San Rafael, California.

Dr. C. J. DuBois was a member of the society for a short time and in 1870 was living in the Island of Capri.

Dr. John H. Churchill came to Saint Anthony for his health, and later removed to New York City, where he resided in 1870.

Dr. Edward A. Barden remained for a time in Minneapolis, but moved later to Alexandria, where he resided in 1870.

Dr. James A. Baldwin remained in the cities but a short time, and then moved to Kansas City, where he was practicing in 1870.

Toward the conclusion of his article, Dr. Ames writes as follows, evidently referring to himself:

"One is here today who saw this locality in its infancy; then it was listening to the voice of praise of the great organ of nature. That member took an active part in the organization of this Society, and has given to its aid and support since it was formed. He will soon go out and you will write up his record."

The above appears a very modest statement to be made by one who had founded the society, and had served it so long and so prominently. At some time previous to the death of Dr. Ames, at the request of his children, he wrote his biography in a little booklet, which afterwards was in the keeping of Mrs. Ames.

In looking through this book it is notable that Dr. Ames refers infrequently and very briefly to his medical experiences, but apparently took great pride in his relation to the Masonic Brotherhood, to the founding of the Horticultural Society, and to the political offices which he had held. Probably he assumed that his very great interest in medical matters would be taken for granted.

He was the first president of the permanently organized Old Settlers organization (announced in *State Atlas* of January 16, 1867), was foreman of the Grand Jury in the first court held by Judge Meeker after the organization of Hennepin County, and was president of the Minneapolis Farmers Club, and of the Hennepin County Bible Society. In November, 1851, Dr. Ames called the Masons together and subsequently established Cataract Lodge, and was its Grand Master on February 3, 1853, and was also subsequently Grand Master of the Grand Lodge of Minnesota, and was one of the ruling elders of the First Presbyterian Church organized here.

The *Tribune Directory* of Minneapolis and Saint Anthony gives the following list of physicians, 1871-1872:

<i>Allopathic</i>	<i>Eclectic</i>
Ames, A. E.	Blecken, Charles H.
Cummings, Ralph W.	Elliot, A. F.
Evans, O. J.	Elliot, J. S.
Goodrich, C. G.	Haynes, S. C.
Hammond, J. H.	Kimball, B. W.
Hill, N. B., and Lindley, A. H.	Loar, Jacob
Hutchinson, W. F.	Stanton, W. B.
Johnson, Geo. B.	Walcot, A. P.
Kimball, H. H.	Talbot, A. V.
Linn, J. J.	
McLain, J. L.	<i>Homeopathic</i>
Phillips, E.	Goodwin, D. M.
Rouse & Johnson	Hatch, P. L.
Teengs, W. J.	Humphreys, Otis M.
Chute, S. H.	Huntington, T. R.
Johnson, A. E.	Leonard, W. H.
McBain, A. E.	Penneman, W. A.
Ortman, A.	
Rouse, W. H.	<i>Miscellaneous</i>
Stockton, E. H.	Etzler, C. H.
Townsend, G. F.	Hale, Miss Mary
	Reinhold, F. K.
	Smith, James A.

The *Tribune Directory* for 1873-1874 says:

"Hennepin County Medical Society was organized in 1855 and is in an interesting and satisfactory condition. Its president is the very oldest physician and surgeon now practicing in Hennepin County and a gentleman well worthy of the honor of the position. Meetings are held every two weeks at the office of one of the members. Officers are: A. E. Ames, President; N. B. Hill, Vice President; Geo. B. Johnston, Treasurer; O. J. Evans, Secretary."

The *Daily Tribune*, Friday, June 6, 1874:

"The Hennepin County Medical Society met at Dr. Ames' office and after reading the minutes of the last meeting elected Drs. Salisbury and Bedford as members of the Society, after which the election of officers took place. Dr. A. E. Ames was unanimously elected president; Dr. Charles Simpson, vice president. Dr. C. C. Clark, secretary; and Dr. Bedford, treasurer. Committee on Ethics—Goodrich, Lindley, Johnson. Membership—Linn, Rogers, Phillips. Printing—Smith, Salisbury and Ortman."

Campbell and Davison's *Directory* gives a list of officers for the year differing decidedly from this, and being practically identical with those of the year before. Here is the list: A. E. Ames, president; N. B. Hill, vice president; O. J. Evans, secretary.

Dr. A. E. Ames died on September 23 of this year (1874) and the following

history of his life is taken partly from a contemporary account in the *Tribune* and partly from *Minnesota Biographies*:

Dr. A. E. Ames was born in Colchester, Vermont, in 1814. His parents were poor and as a child he was so sickly that he was not expected to grow up. Later the family moved to Orwell, Ohio, and in the common schools of these two places he acquired his education. While teaching in 1834 he met Miss Martha Pratt, whom he married in 1836, and a month after his marriage he went to Chicago, then a town of 3,000, mostly half-breeds. From there he followed the Indian trail west to a place later called Amesville, now Garden Prairie. Here he took a claim of 160 acres, and built a log house. In April, 1837, he returned to Chicago and worked for \$52 a month at brick-making. On November 25, 1838, he walked to Vandalia, then the capital of Illinois, and was there introduced to Alex. Field, Secretary of State, by Stephen A. Douglas, and was appointed Deputy Secretary of State and also Private Secretary to Governor Carlin; and in these positions he earned \$6 a day. In 1839 he was again Deputy Secretary of State, Secretary to the Governor, and chief of the staff of clerks, earning thus \$10 a day.

In 1840 he began to attend medical lectures at Rush, and in 1841 he studied with Dr. Maloney of Belvidere. At this time he was in very poor health. He was elected a member of the House of Representatives of Illinois in 1842. In March, 1843, he was made postmaster at Belvidere. In July, 1844, he resigned and moved to Roscoe, Illinois, where he began the practice of medicine, and was made postmaster December 16. In February, 1845, he graduated from Rush. In 1849 he was elected State Senator, and made paymaster general on the Governor's staff. He started three Masonic lodges in Rockton, Roscoe, and Rockford, Illinois. In October, 1851, he left Roscoe for Saint Anthony, going by wagon from Roscoe to Galena, thence by the famous Dr. Franklin No. 1 to Saint Paul. He secured a permit to make a claim on the Reserve, now Minneapolis, and in November, 1851, built his claim cabin on the lot now occupied by the Court House. Immediately following his arrival he entered into a partnership with Dr. Murphy of Saint Anthony. In the spring of 1852 he brought his family from Illinois. The same year he was made contract surgeon at Fort Snelling and in October was elected to the territorial legislature. October 10, 1854, he was made probate judge. In January, 1856, he was appointed postmaster. In 1857 he was chairman of the committee on school lands and university, and in 1860 was a member of the State Normal school board, serving during the organization of that system. In 1861-1862 he delivered a course of lectures before the high school of Minneapolis on anatomy and hygiene, being thus, doubtless, the first to give public instruction in Minnesota on a medical subject. In 1852 he went east to visit the hospitals. In 1868 he again went east, and then to California, where he had some idea of remaining, offering his home and property here for sale, but returned. "He was always actively interested in all educational matters. In fact, he was never idle and scarcely ever allowed to remain in private life. He was a member and almost always a leader in the medical society." This is almost the only reference in the above accounts to his medical life, though, curiously enough, he was probably president of Hennepin County Medical Society practically continuously from its inception in 1855 to his death in 1874, almost twenty years.

Dr. Ames was a member of the American Medical Association, had been president of the Alumni of Rush Medical College, and was much devoted to

his profession, to which he had given many years of hard labor. In a memorial notice given in the Transactions of the Minnesota State Medical Society for 1875, Dr. O. J. Evans says of him: "The most prominent probably of Dr. Ames' characteristics was that most commendable of all the graces—charity. During an acquaintance of nine years, I think I never heard him speak an ill word of any person."

On February 5, 1875, occurred the death of Dr. Nathan B. Hill, who, though not one of the founders of the Hennepin County Medical Society, was one of its earliest and most influential members. Dr. Hill was born in Randolph County, North Carolina, on May 13, 1817. After graduating from Haverford College, near Philadelphia, he entered mercantile life with his father, but later decided to enter medicine, and attended Jefferson Medical College during the session of 1842-1843. In May, 1845, he married, and in the winter of 1847-1848 moved to Cincinnati, where he attended lectures at Ohio Medical College and graduated in 1848, after which he returned to North Carolina and practiced until 1861. He was a strong anti-slavery man and was interested in the underground route for the freeing of slaves, to the great detriment of his practice and danger of his life. In May, 1861, in company with Dr. Lindley, he came overland to Indiana, crossing the Ohio River at Louisville, and in September came to Minneapolis, where he and Dr. Lindley formed a partnership which continued to the death of Dr. Hill. At the time of his death he was president of the State Medical Society, the annual meeting of which he had called to order but a few hours before his death. His address was read by Dr. Hewitt. Dr. Hill was a devout member of the Society of Friends, and was a man of fine susceptibilities, generous impulses, and of the highest integrity, and, with his natural ability, his superior education and kindly ways, he became a very prominent physician in this community.

There are many others among the older physicians of whom special mention might be made did the limits of this paper permit, but it will not be considered an invidious distinction, I think, if I refer particularly to the following:

Dr. C. W. LeBoutillier was a native of the island of Jersey, emigrated to this country about the year 1850 and settled in Iowa. In 1853 he came to Saint Anthony and commenced the practice of medicine, and soon became known as an honorable, skillful and successful physician. On April 29, 1861, he was commissioned as assistant surgeon in the 1st Minnesota Infantry, and the *State Atlas* of July 24, 1861, carried the news of his death at the battle of Bull Run, and gave an account of his life and work; but a telegram of August 16 announced that he was alive and well, had elected to remain with his wounded and was a prisoner in Richmond. The ten federal surgeons in Richmond were divided into two groups and Dr. LeBoutillier was placed in charge of one group. In this position his assiduous care and kindness to the wounded won grateful praise from those to whom he ministered. The *Pioneer* of September 17, 1861, contained a letter from him, dated August 15, and described some of his surgical experiences among the soldiers. Paroled, he returned to Minnesota, where he remained with his family until the time of the Indian outbreak, when he became surgeon of the Ninth Regiment, October 10, 1862, and went to Saint Peter, where he remained on duty until his death April 3, 1863, aged about thirty-seven. He was buried with military honors in Saint Anthony. Dr. LeBoutillier left the record of an honorable and successful physician, a good citizen and a brave soldier. He seems to have been held in particularly high esteem by his fellow practitioners.

Dr. A. Ortman located in Saint Anthony in 1857, was later active as a city and county physician and was one of the oldest members of the State Medical Society, of which he was made an honorary member without dues. He was a very excellent man, notable for his high ethical standards and kindly disposition. Owing to the development of cataracts, he became blind several years before his death.

Dr. A. H. Lindley was born in North Carolina in 1821. He came to Minneapolis in 1861 and began practice with his brother-in-law, Dr. N. B. Hill. He was a well educated, reliable, conscientious and successful physician, prominent in the sanitary interests of the city, and its first health officer. As a result of judicious investments he became very wealthy, and died in Minneapolis at the advanced age of nearly eighty-four years.

Levi Butler came to Minnesota in 1855 from Indiana. He was married and had practiced ten years before his arrival. He had a moderate fortune and became interested in educational, moral and temperance activities. In 1861 he recruited a company of volunteers, and was made captain and afterwards surgeon of the Third Regiment of Minnesota Infantry, of which his company was a part. He was commissioned November 11, 1861, and went south. When his regiment surrendered at Murfreesboro he returned to assist in the suppression of the Indian outbreak. He later rejoined the service and was in campaigns in Kentucky and Louisiana. He resigned and came home in September, 1863. Dr. Butler was one of the large number of tuberculosis patients who came to Minnesota in search of health, and it was on account of a return to his old trouble and a condition of protracted ill health that he was discharged in 1863. In the following year he was appointed by the governor to visit southern camps and hospitals to improve sanitary conditions and relieve the suffering of sick Minnesota volunteers. At the return of peace he did not engage in practice but went into the lumber business with T. B. Walker and H. W. Mills, under the name of Butler, Mills and Walker. He died in 1868.

Dr. William H. Leonard was born in Mansfield, Connecticut, December 2, 1825, and graduated from Yale Medical School in 1853, and settled in Minneapolis in 1855. The initial meeting of the Hahnemann Medical Society was held in his office and he was the first president of that organization. He was successively assistant surgeon and surgeon to the Fifth Minnesota Regiment of Infantry, and served from November 22, 1862, to September 6, 1865, and was discharged with his regiment. He died in the city of Minneapolis, April 9, 1907.

Dr. A. A. Ames was graduated from Rush Medical College in February, 1862, and shortly after began practice in Minneapolis. In August, 1862, he helped to raise Company B, Ninth Minnesota Infantry, himself and brother enlisting. The same month he was commissioned assistant surgeon to the Seventh Minnesota and departed for duty on the frontier where the Indian war was raging. In the fall of 1863 he went south and engaged in field service until the end of the war and was mustered out at Ft. Snelling August 18, 1865. In March, 1868, he went to California and engaged in newspaper work. In September, 1874, he was summoned to the death-bed of his father and, in company with Dr. Salisbury, took up his father's practice. A card in the *Minneapolis Daily Tribune* of May 25, 1867, announced that Dr. A. A. Ames will hereafter attend only surgical cases, diseases of a surgical nature and office practice, the first instance of surgical specialism I have found. He later

entered politics, and through his efforts the Minnesota Soldiers' Home was founded.

Dr. George Keith was born in 1825 and graduated from the Medical College at Woodstock, Vermont. After living in New York two years he decided to go to Minneapolis, where he had two brothers. In Minneapolis he began the practice of dentistry and medicine, but devoted his attention almost wholly to the former. He was a member of the First State Legislature of 1858-1859. During the Indian war of 1862, he was surgeon to the expedition sent to the relief of Ft. Abercrombie. In 1863 he was made provost marshal for the Second District of Minnesota, a position he retained until the end of the war. He resumed practice and was made postmaster in 1871 and reappointed in 1875.

Dr. O. J. Evans was born in New York in 1840, and graduated from the Albany Medical College of New York, and went immediately to the front as assistant surgeon to the Fortieth New York Volunteers. The following summer he became surgeon to the regiment and was detailed on the operating staff of the brigade, which duty he discharged until the end of the war, when he was made Chief of the Medical Department of Farnsville, Virginia, where there was a cluster of Confederate hospitals filled with Union and Confederate wounded. Of these hospitals he had general supervision. He took part with his regiment in the Grand Review in 1865 in Washington, and was mustered out some time later. In September, 1865, he came to Saint Peter, and ten weeks later removed to Minneapolis where he remained in practice up to his death on October 17, 1916. He served two terms as city health officer of Minneapolis, was a member of the Board of Education, and a member of the legislature, and was largely interested in business as well as in professional matters.

There are many other members of the profession whose experience in the war preceded their arrival in Minneapolis, and these include, among others, Drs. Abbott, DuBois, Phillips, Goodrich, and others.

Dr. C. G. Goodrich came to Minneapolis in 1868, and at once entered on an extensive practice. He was wealthy when he came, and invested largely in real estate. He was a modest, truthful, faithful, and generous man and was the first elected president of Hennepin County Medical Society following the death of Dr. Ames.

Daily Tribune, June 5, 1875:

"The fifth annual meeting of Hennepin Society was held at the office of Dr. Evans in his new block on Bridge Square last evening. Nearly all the members were in attendance, the meeting being particularly important and peculiarly interesting. Drs. R. J. Hill and A. H. Lindley were duly elected and installed members, after which the election of the officers for the ensuing year took place. The following was the result: President, C. G. Goodrich; Vice-president, O. J. Evans; Secretary, A. S. Salisbury; Treasurer, W. C. Bedford. At the close of the election Dr. Simpson, the retiring president, made a few apt and timely remarks as did also Dr. Evans, who, in the absence of the president in the east getting married, acted as presiding officer.

"The fee bill for the Society was discussed and slightly amended, among other changes it being resolved to charge an invariable fee of \$25 for holding a post-mortem examination.

"Dr. Clark was appointed essayist for the next meeting and Dr. Simpson for the one following, after which the meeting adjourned."

The above note on post-mortems may have some connection with the following very unpleasant article which had appeared in the *Tribune* of December 3, 1872:

HISTORY OF MEDICINE IN MINNESOTA

"The Minneapolis Post-Mortem Club.—The Club met today pursuant to adjournment, Dr. A. S. S. Jones in the chair. Dr. D. M. Phule, Secretary, read the minutes of the last post-mortem. Committee on Mortality reported two deaths since last meeting.

"Dr. I. M. Some introduced the following resolution: That the H. O. G., this city, be instructed to notify this Club of all deaths occurring within the limits of the city.

"And, resolved that for the benefit of science this Club shall immediately take possession of the bodies and post-mortem the same with as little delay as practicable, that being the only method of arriving at a correct diagnosis in any case.

"And, resolved that with the sole object of enlightening the benighted public upon scientific medicine, the proceedings of this Club be published in the daily papers in case they do so gratuitously. * * *

"Gentlemen, you befog your own brains. Every post-mortem made by this Club since the organization has ventilated your own ignorance. The people ask for a little more knowledge of disease before death and fewer post-mortems; for less advertising and less braggadocio and more careful, earnest practice. The disgusting frequency of post-mortems in this city is a disgrace to the profession, which the people will ere long rebuke."

It was about this time that Dr. Tanner, an herb doctor of Minneapolis, acquired widespread notoriety through his fasting demonstration, which appears to have been an advertising scheme carried on in Market Hall at Hennepin and First Avenue South. I have not located the exact date or description of Tanner's activities. After the close of his fasting*exhibition he went on the lecture platform, and seems to have disappeared from Minneapolis.

(To be continued in the February issue)

ARITHMETIC PROBLEM

If the average case of minimal tuberculosis admitted to the sanatorium stays eight months, and the average case of moderately advanced tuberculosis stays twenty-three months, how much could be saved by early diagnosis?

In Connecticut where it costs about \$1,000 to keep a patient in the state sanatorium for a year and where only 10 per cent of the admissions are in the minimal stage, it is estimated as hundreds of thousands of dollars by the Connecticut State Tuberculosis Commission.

Unfortunately, the situation in Connecticut is not unique among the states. Everywhere admissions to sanatoria are largely in the later stages, and everywhere the result is a longer hospital stay—a tragic waste whether human suffering, disability or money is considered.

BERTRAM S. ADAMS, M.D.
President, Minnesota State Medical Association

President's Letter

MEDICAL science today has attained its highest development in world history. Never before has the physician been able to do so much to aid the sick, injured or disabled.

Our own country leads the world in sickness prevention, in lowering the incidence of preventable disease, in reduction of time loss due both to injury and disabling disease, and in lengthening the average span of life. These things have been accomplished, in large measure, by our American system of medical practice which allows for freedom of action by the doctor and also provides the stimulus of competition.

These facts are everywhere acknowledged and, in spite of them, some of our people would do away with the American system of medical care and put in place of it some form of government controlled medicine, European style. Among those who clamor loudest for a change are the politicians who regard it as a source of votes and the social workers who see in it a means of obtaining unlimited medical care for the very poor, not realizing that it also means a cheap and inferior service.

We must remember that the European systems had their beginning with Bismarck, who needed votes to defeat the opposing political party in 1883; and that Lloyd George had the same objective when he started the Panel system in England in 1911.

We must remember that 1940 is election year in the United States, also, and we must watch out for comparable attempts to change our own system in the coming campaign.

Dr. Mountin, assistant to Surgeon General Parran of the United States Public Health Service, expressed his confident belief, on a recent visit to Minnesota, that the next Congress would pass a health bill. The Wagner bill of last year was a trial balloon only, he said; but even that bill would have passed if the usual pressure had been applied. Physicians' organizations were opposed to that bill and would be opposed to any measure drawn up on similar lines, not only because of the exorbitant costs but because they do not believe such a bill would aid good medical practice.

There is no doubt that medical practice has declined in efficiency wherever the government has been in control; that preventable diseases are increasing in prevalence in European countries; that time loss from disease and injury has grown; that medical services are poor in quality and that there is little incentive for the physician to study and improve himself. Not only is the service in general poor, but the doctors themselves are underpaid, overburdened with petty detail and forced to spend their time in making interminable reports. They are also forced too often to perjure themselves in making allowances for disability in order to retain their panel clientele and they must curry favor with politicians in the government positions. If another health bill is introduced this year in Congress it must be examined closely. If it is the Wagner bill of last year in new dress or a similar measure—every doctor must exert his utmost effort in time, money and public propaganda to defeat it.

BUSINESS MANAGER

J. R. BRUCE

Volume 23

JANUARY, 1940

Number 1

1939-1940

WITH the arrival of a new year comes the
urge to reflect on the past year and to an-
ticipate the year to come.

World War II has been in progress for four
months with strange alliances and war activities
limited to the sea in a type of warfare directed
toward subjugation of the enemy through eco-
nomic pressure. A prolonged conflict can only
prove disastrous in its political, economic and
moral aspect to both winner and loser.

While our attention has been shifted from do-
mestic to foreign affairs, and we can feel truly
thankful that as a nation we are at peace with
the world, we have our own economic problems
which are vital in their importance.

On the pretext of emergency need Congress
has delegated its powers to the executive branch
of the government, which has been nothing loath
to apply experimental methods, which have large-
ly been contrary to established principles of
finance and the proper sphere of governmental
activities. As a result every type of business has
found the government a competitor. Proposals
such as the Wagner Bill have emanated from
governmental circles, involving the expenditure
of millions, yes billions, of the taxpayers' money
for the development of governmental activities in
medical care. As preparation for such activities
an attempt was made by the Department of Jus-
tice to discredit the medical profession. The re-
fusal of Congress to pass the Wagner Bill at the
last session offered proof of the tendency of
Congress to reassert itself. We have reason to
believe, however, that some proposal resembling
the Wagner Bill will again be introduced in the
Congress just convened. It behooves the medical
profession to make available the facts regarding
medical needs of this country and the type of
medical service which will best serve the country.
The A.M.A. has published its platform, so the
public knows our point of view. The National
Physicians' Committee for the Extension of
Medical Service affords the medium for dissem-
inating information and deserves the support of
the entire medical profession.

Medical care is one of the important items in
the life of any individual. Numerous European
governments have provided various types of
medical care for their citizens, none of which
would be acceptable to American citizens. We
fear that in the coming Republican and Demo-
cratic conventions the temptation to include a
party platform plank providing certain govern-
mental medical care will be too strong to resist.
If one party does so the other is likely to go the
first one better. The advisability of any such pro-
cedure should be decided on its merits and the

proposal should not be made a political issue in the coming election.

MINNESOTA MEDICINE wishes to take this opportunity of expressing to the officers and members of the Association its appreciation of the co-operation manifest the past year and in pledging its continued support of all of the activities of the Association the coming year, and to wish all our members a prosperous and Happy New Year.

CENTER FOR CONTINUATION STUDY

THE Center for Continuation Study at the University of Minnesota is unique. So far as we know there is no similar center anywhere in the country. The beautifully equipped headquarters building in the nature of a small first class hotel with moderate prices, the concentration of courses and the personnel of the instructors provides one desirous of adding to his knowledge in his particular field, the opportunity for doing just that at a minimum of time and expense.

A generation ago physicians found it worth while to take a trip to Vienna for a few weeks of postgraduate study. Then there was little opportunity in this country to obtain postgraduate work of high order in a short space of time. Now there is little or no opportunity abroad and teachers and material in this country are unsurpassed.

That the Continuation Center is dispensing postgraduate study opportunities of high order is attested by the enrollment so far. The program of the winter quarter appears in this issue. Full use will doubtless be made of the opportunity afforded general practitioners especially to obtain instruction in subjects of special interest.

THE MINNESOTA MEDICAL FOUNDATION

THE appearance of the first issue of the *Bulletin of the Minnesota Medical Foundation* in November, 1939, is evidence of beginning activities of the Foundation. In November, too, the first meeting of the Advisory Committee and others interested in this new organization was held on the University Campus and helped the Committee on Organization to draw up By-Laws.

The Foundation, as was stated in an editorial in our November number, is an organization of

medical alumni students and friends of the medical school of the University of Minnesota, whose purpose is primarily to further medical education in undergraduate, postgraduate and research activities.

The *Bulletin* will keep alumni posted regarding the activities of the medical school and the alumni. This, however, is only one activity of the Foundation. Contributions are being received, the income from which will be used to provide scholarships, loans to students and the means for carrying on medical research. Contributors of \$1,000 or more will be designated patrons, while life membership can be obtained through a contribution of \$100. A substantial source of support, however, will come from annual membership dues which have been set at \$10. While the organization provides the mechanism for the devotion of large bequests to medical progress in Minnesota, a large membership is absolutely necessary for its success.

Memberships may be obtained from the office of the Minnesota Medical Foundation, 132 Medical Science Building, University of Minnesota, Minneapolis.

CONSULTANTS

CONSULTATION is often desirable. Alas, consultation too often results to the detriment of the physician referring the patient. This should not be. The ideal relationship between physician and consultant results in help, not harm to the former.

Charlatans and quacks do not refer patients. Imitators of charlatans and quacks among inferior physicians do not refer patients. The higher type of physician is more apt to refer patients than the lower type. What leads him to refer a patient? It is honesty, conscientiousness, keen concern for the welfare of the patient, and desire to do the best for him. Referring a patient is not necessarily a confession of weakness nor of inferiority; it may be an indication of strength.

It is perfectly true that no higher motive than self interest need induce the consultant to be helpful to the physician who refers the patient. If confidence in the referring physician is augmented, he will be in a position to refer more patients.

More mistakes are made by the referring phys-

ician not accompanying the consultant in his visit to the patient. Physicians in the preceding generation were very meticulous in the manner in which consultations were carried out. The referring physician entered the room first and on leaving the room, followed the consultant. The reason was obvious. They then retired to discuss the patient in private. The discussion of the case in private was a fundamental part of the consultation which might well be perpetuated. Telling the patient about findings or giving advice on the part of the consultant is not to be tolerated unless he is specifically requested to do so.

The consultant must feel a kindly attitude toward the ability of the referring physician. After all, he may be the better physician. Any lack of respect for the referring physician is sure to color the consultant's remarks to the detriment of the former in the eyes of the patient.

The referring physician places a very precious possession in the keeping of the consultant: his reputation and prestige. The trust should not be betrayed. The consultant has a right to feel honored at being consulted. His words and actions should show every respect for the patient's physician. Any other attitude often acts as a boomerang to the discredit of the consultant.

The whole purpose of a consultation is the patient's welfare. Only by careful observance of the details mentioned will the patient obtain the greatest benefit from a consultation and credit accrue to both physicians.—C. G. K.

THE BACH TRADITION

BECAUSE there were forty-nine good musicians, twenty of them noted, in seven generations of the Bach family it has been very generally considered to be, as one writer states, "the most remarkable instance of hereditary genius in all history." It certainly looks like it, but one can't help but wonder if environment did not play an important part in the production of this remarkable situation.

They lived in an atmosphere of music, for Thuringia, where they were born and lived from generation to generation, was traditionally musical, and close by, in Saxony, was the most famous organ building district in the world. Then, from old Veit Bach, the baker who only played the zither in his spare time and died in

1619, down to the last Bach of any musical consequence, in a period of two hundred and fifty years, they lived in their own family atmosphere of music, teaching their younger brothers and sisters, their children and their children's children.

In this firmament of musical talent appeared a star of the first magnitude, the great Johann Sebastian Bach. In his period all musical instruments were still very primitive, as compared with those of today, and it is difficult to understand how he, thus handicapped, could produce music which today stands unmatched, at the very top. His preludes and fugues for the organ call for all the resources of the modern instrument and only a few performers can really play them. He was the father of twenty children, only two of whom became well known in music. In another hundred years the strain died out.

The question of environment is interesting in connection with this unique group of talented people and its single genius, but again we are puzzled when we think of the many others whose genius survived the most uncompromising obstacles. Perhaps it's the chromosomes, after all.

—G. C.

PRESCRIPTIONS REQUIRED

THE new Federal Pure Food, Drug and Cosmetic law is now in effect.

The F. D. A. has issued a regulation prohibiting the sale of the following drugs, except on prescription: acetanilid in combination with bromides if the dose is more than $7\frac{1}{2}$ grains a day, aminopyrine and its preparations, benzedrine sulfate, cinchophen and its preparations, neocinchophen and its preparations, sulfanilamide and its preparations, thyroid and its preparations.

Such a ruling is a step in the right direction in an effort to stop promiscuous use of drugs and self-medication.

To be effective 100 per cent, however, it is the duty of the physician to write prescriptions for the above mentioned drugs and the pharmacist shall not dispense these drugs except upon prescription.

Coöperation of all allied medical professions is needed in this work.

—J. S.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association

W. F. Braasch, M.D., Chairman

OFF TO A GOOD START

The National Physicians' Committee for the Extension of Medical Service is off to a good start.

Information has been received to the effect that the movement is being enthusiastically backed by large numbers of physicians in all parts of the country. Not alone have they backed it with their moral support, but, to a surprising degree, with generous contributions. The widespread support of the objectives of the Committee promises well for its future success. While it is still in the formative stage, its future activities are already being planned.

Every member of the medical profession who sends in his name and contribution for membership automatically becomes a member of this nation-wide committee.

The active coöperation of every physician who enrolls will be sought. Literature will soon be sent out in a form attractive to the layman and all members of the Committee will be counted on for its distribution. The combined efforts of its membership should be a powerful factor in the future support of American medicine. Have you filled in your application blank?

A Minnesota Branch of the National Committee has been formed in order to expedite the activities of the National Committee. Its Executive Committee has had several meetings and will undoubtedly be of great aid in furthering the national objectives.

MINNESOTA BRANCH

It is of interest to note that the first state branch of the National Committee for Extension of Medical Care in the country was organized in Minnesota.

It was formed under the chairmanship of Dr. F. J. Savage of Saint Paul and now embraces as members and contributors, medical leaders from all parts of Minnesota.

The Minnesota organization will serve as the local agency for distribution of literature to members and it will enlist the aid of key representatives of the other professions who are interested as citizens and as professional men in the philosophy behind the physicians' movement.

To Spread Information

The Minnesota branch will carry out the general program of the national organization. It will throw its influence behind any local extensions of medical service that may be shown to be needed in Minnesota and it will spread information to all parts of the state on the kind and quality of services available in Minnesota; on the extraordinary progress made in Minnesota in the control of communicable disease and the lowering of maternal and child death rates. In these respects and in many other key tests of the adequacy of medicine and the public health services, Minnesota stands at or near the top among all the states of the United States. It is important for the citizens of Minnesota to be familiar with these facts so that social experiments in medicine with their dubious results elsewhere may be properly evaluated in the light of accomplishments here.

Committee Is Independent

It should be noted that the Minnesota branch of the National Committee of Physicians for Extension of Medical Care is in no way fostered by

nor subservient to the Minnesota State Medical Association. It is an independent committee of physicians, organized for special purposes and financed by contributions of its members.

THE COUNCIL MEETS

Marked expansion in the public health education program of the Minnesota State Medical Association will begin in several directions in 1940.

Information about the elementary principles of good health and about available medical services is regarded, on all hands, as an immediate and practical method open to physicians to aid in solving medical-economic problems.

There is a great weight of untreated illness due—not to lack of resources or lack of medical facilities—but to sheer ignorance and neglect.

For Public Education

Increase in facilities and increase in appropriations of funds will not lift this weight; but concentration by medical organizations upon the problem of public education is a step in the right direction and a step upon which all physicians now agree.

Accordingly the Council approved extensions in nearly all activities of the Committee on Public Health Education as follows:

1. A Question and Answer Column sponsored by the committee, will replace the regular health news story which has been sent each week to country newspapers in the state through the Minnesota Editorial Association. The new service will provide opportunity to rural newspaper subscribers to send their questions, a few of which will be published each week, to competent authorities for answer. Rural papers which cannot afford the syndicated health columns will thus receive a free, authoritative service.

To Aid Speakers

2. The Speakers' Library will be enlarged by lantern slides on popular subjects. Slides are frequently requested but until now no appropriations or facilities have been available for supplying them. Committee chairmen will be asked to aid the new Speakers' Library with outlines for specimen talks to accompany the slides.

3. The association's popular radio program conducted by Dr. W. A. O'Brien over WCCO will be enlarged to embrace the smaller radio

stations in many parts of the state. The question of whether local speakers should be utilized is being investigated; also the possibility of making recordings of Dr. O'Brien's talks for re-broadcasts over these stations.

The regular college lecture courses of the association will be continued and the committee will coöperate closely with the Committee on Hospitals and Medical Education and other scientific committees of the association to carry forward and amplify the Coördinated Medical and Public Health Program inaugurated with such success last January. Monthly packets will be continued for the year and the subjects drawn up at a preliminary meeting depart considerably from the 1939 subjects in order to insure interest for the 1940 packets.

"The Only Way . . ."

Minnesota physicians will coöperate closely with the newly organized Division of Social Welfare of the (Department of Social Security) in the solution of all problems connected with medical care of relief clients and recipients of the Social Security Aids.

An advisory committee of the state association was approved by the Council to meet regularly with social welfare officials, Mr. Walter Finke, director, and Dr. H. E. Hilleboe, medical chief. The committee is composed of the following: Drs. A. W. Adson, Rochester; L. L. Sogge, Windom; C. A. Stewart, Minneapolis; W. A. Coventry, Duluth; E. J. Simons, Swanville; with Dr. Hilleboe, Dr. A. J. Chesley of the State Board of Health, and Mr. R. R. Rosell as ex-officio members.

Working Method

A suggestion for a working method of bringing physicians and welfare boards together locally to handle joint medical problems was proposed by Mr. Finke in person to the Council and cordially approved. The County Contact Committees will figure in this plan when it is officially announced and their rôle will be to consult with local welfare officials on medical care for all welfare clients.

"There are many things we don't know yet about our medical relief problem in Minnesota," Mr. Finke told the Council. "We don't know how much money is being spent for medical care in this state, for one thing. We are going to try

to find out what is spent, however, and how it can best be spent. But we shall make no decisions and inaugurate no policies without consulting the medical profession. *As a professional man, myself, I am convinced that the only way we can arrive at a solution of our medical difficulties is through the medical profession.* We began our work by asking for an advisory committee from your body. We shall continue to work only through this committee and your association."

Teaching Demonstration

An obstetric teaching demonstration and home delivery service to be used in connection with obstetric teaching at the University Medical School was proposed by Dr. A. J. Chesley, secretary and executive officer of the State Department of Health, as a means of utilizing an appropriation which may be made available to Minnesota out of unexpended funds of the Children's Bureau, provided that agency approves the proposal. This teaching service would give medical students an opportunity, not now available, of making deliveries in homes in the vicinity of Minneapolis. The object is, of course, to prepare students for obstetrical emergencies they will meet in practice.

The Council expressed its interest and requested that the program be referred for approval to the Hennepin County Medical Society.

Does Not Initiate Legislation

The United States Public Health Service does not initiate legislation, Dr. J. W. Mountin, Assistant Surgeon General of the United States Public Health Service and guest of Dr. Chesley, informed the Council. "Legislation in social fields arises with outside groups and is often well on the way to committee hearings before health service officials are informed of it. As you know, we are specifically prohibited from either initiating or supporting any legislation and the policy of the Public Health Service is based upon programs formulated by state health officers."

On the other hand, the organization of State Territorial and Provincial Health Officers can and does take an active interest in legislation. For instance, the health officers' association is currently opposed to transference of Industrial Hygiene and Occupational Diseases from the public health service to the Department of Labor

and also to removal of the Division of Vital Statistics from the health service.

Cancer Education

Thirty thousand people all over the United States took part in the Women's Field Army Against Cancer program last year, according to Dr. F. L. Rector, field secretary of the American Society for the Control of Cancer, who spoke briefly on the work of the women's organization. Forty-eight thousand talks were given about cancer, 42,000 of them by physicians, the others being organization talks by society representatives. The new women's organization has been in existence for three years. It raised \$165,000 during its third year, of which 30 per cent went to the National Society for the Control of Cancer and 70 per cent was retained for local cancer education work. Some 4,000,000 pieces of literature were distributed on cancer last year and 1,500 exhibits were shown at fairs and meetings.

Neither the national cancer organization nor the Women's Field Army is in the clinical field, Dr. Rector said. Its program is entirely under control of physicians and no clinical use will ever be made of funds raised in Minnesota unless the Minnesota physicians ask for it.

To Study Fees

Fees for medical relief are far from uniform in various parts of the state. Discussion of inequalities and occasional difficulties that arise from them prompted a request by the Council for a study of the situation on the part of the Committee on Low Income and Indigent Problems. The committee will accumulate figures and data not only on fees but on all phases of the relief problems from the point of view of physicians. Information thus gathered will be presented at the County Officers' meeting scheduled for February.

New Committees

Two timely new committees have been appointed by President B. S. Adams with Council approval.

One of these, the Committee on Vaccination and Immunization, will take the lead in a coördinated state-wide effort on the part of members of the association to carry on community vaccination and immunization programs. Dr. L. R. Critchfield, formerly chairman of the Committee

on Public Health Education, was appointed to chairmanship of the new committee and a state-wide plan drawn up at the request of the Council by Dr. C. A. Stewart of Minneapolis, was tentatively approved and referred to the new committee.

The second is the Committee on Industrial Hygiene and Occupational Disease, of which Dr. J. L. McLeod of Grand Rapids will be the first chairman.

For Civil Service

A special committee will also be appointed by the president and the chairman of the Council to work with the new Civil Service Board in drawing up examinations for physicians who engage in state institutional work.

Public Health Meetings Approved

An expression of official approval for promotion of vaccination and immunization was requested by the State Sanitary Conference at an earlier meeting. The approval of the Council was given and the recommendation made that county and district medical societies hold at least one meeting each year on public health problems. Speakers for these meetings will be provided on request by the State Board of Health.

ON MEDICAL ECONOMICS

Following a plan developed with great success two years ago, subcommittees of the Committee on Medical Economics met separately and then joined in a general dinner meeting of the entire committee recently in Saint Paul.

Below are brief abstracts of reports made by subcommittee chairmen at the dinner.

We Are Fortunate

Dr. W. F. Braasch, chairman: A thorough trial is being made of health insurance by medical societies in many states. We are fortunate in Minnesota that no political emergency exists which might serve to push us into premature experimentation with these new forms of service. Our best policy, it seems to me, is to watch developments in other states and avoid costly experiments.

In the meantime, it appears that a closer cooperation is highly desirable between physicians and county welfare boards throughout the state.

This is one effective method of seeing that the under-privileged receive adequate medical service under our present system of practice in Minnesota.

For Up-to-date Information

Dr. W. A. Coventry, Duluth, chairman of the Sub-Committee on Low Income and Indigent Problems: At the direction of the Council, a questionnaire has been compiled to send to all members of County Contact Committees. By means of this questionnaire we hope to get up-to-date information on details of handling medical relief in all parts of the state so as to lend assistance where it may be needed.

In that connection it is interesting to note that physicians in Wright county, after careful study of the plan, decided not to enter into any co-operative arrangement with the Farm Security Administration to provide medical care for Farm Security clients (See *Medical Economics Section* for December). Existing machinery was regarded as adequate to care for these clients and the need was not acute enough to warrant so uncertain a departure from ordinary methods of care.

Marked Progress

Dr. B. J. Branton, Willmar, Chairman of the Medical Advisory Committee: The Medical Advisory Committee has made demonstrable progress, as witnessed by the greatly improved malpractice situation in Minnesota. The work of the committee is particularly noticeable in the decided change which has come about in the last few years in the attitude of lawyers toward the medical profession. In marked contrast to the condition a few years ago, there is now close coöperation between the two professions.

Clinics Planned

Dr. T. H. Sweetser, Minneapolis, Chairman of the Sub-Committee on State Health Relations:

The American Legion plans to launch a program of child welfare which is to provide speakers on child welfare and Child Welfare Clinics in Minnesota. If the plan is carried through, it should be done with caution and with strict medical supervision. It is our suggestion that the clinic program be referred to the Committee on Child Welfare of the Committee of Public Health Education for study with the recommen-

dation to the Legion that nothing be done without consulting the Child Welfare Committee.

Problems in Ethics

Dr. L. A. Buie, Rochester, Chairman of the Sub-Committee on Medical Ethics:

I believe that this committee has a function and that something valuable can come from its work, in spite of the fact that there was a negligible response to a letter sent to all county medical secretaries by this committee asking for information concerning infringements of the code of ethics. A few instances have come to our attention through other sources and the members involved have been interviewed with entirely satisfactory results. It needs only a slight infringement of ethics to produce a malpractice case and anything that we can do to prevent such infringements is of great assistance to the individual involved, as well as to the organization. It has been suggested that we might draw up artificial problems based upon actual instances and publish them for the information of all members in MINNESOTA MEDICINE.

Position Endorsed

Dr. Stephen Baxter, Minneapolis, Chairman of the Sub-Committee on Industrial Relations: Relations between the profession and the better insurance companies are satisfactory. The committee fully endorses the position of the state society against the practice of medicine by fraternal orders.

INSURANCE PITFALLS FOR PATIENTS

The success of the non-profit Minnesota Hospital Service Association has pointed a new way to profit for commercial insurance companies.

These companies are writing hospital insurance policies for a large number of persons, and physicians who are asked about these policies should be informed of possible pitfalls into which unwary subscriber-patients may tumble.

The financial standing of any insurance company can be checked with the insurance commissioner but it is also necessary to study the policy and methods even of the most reliable of them.

All policies make certain necessary restrictions upon payment of benefits, some more than others. In most cases it is important to study the policy closely since many exceptions are cloaked

from casual perusal and appear to leap into being only when benefits are refused.

Sinus Rider

Still others appear to have a disconcerting habit of attaching riders to the original contract and sending them to the subscriber *after* his application is made and noted and the premium accepted. Thus, there is one recent instance on record of a subscriber who had noted a sinus infection in her application. The sinus infection was the only ailment she had been obliged to report in her application. The first policy shown her had contained no mention whatever of sinus infection; but a rider which informed her that hospital benefits would not be paid for sinus trouble was attached to the policy sent her afterwards from the main office.

If she had confessed to dyspepsia or rheumatism or fallen arches a different kind of rider might conceivably have accompanied her policy.

Mail Order Business

The company which sold the policy minus sinus privileges is actually old and reliable and well known. Other companies which may or may not be approved by the insurance commissioner are now embarking upon a mail order business in hospital insurance in order to take full advantage of what looks like a profitable field.

It works this way. The applicant sees an advertisement, writes for information and receives, along with a contract, a glowing promise of coverage for *all* hospitalized illness plus the doctor's bill while he is in the hospital, all for \$3.65 a quarter. He signs and returns to the company the sheet which bore the sweeping promises. He retains in his possession only the policy which, on closer inspection, reveals that benefits are actually available only to the fortunate and the adroit. The owner of this policy is protected against hospital bills for all illnesses except peptic ulcer, cancer, heart disease and accidents due to external violence, to name only part of the exceptions—a complete list of which covers most of the afflictions which get people into hospitals. It is part of the mail order technic that the policy should be in force and the applicant liable for the premiums if the policy is not returned to the insurance company within ten days. Thus, through carelessness or accident the hapless answerer of "ads" may find himself the unwilling owner of an all but worthless document for which he will pay an exorbitant fee.

Coverage for Doctor

It should be noted in considering abuses of hospital insurance that there are also non-profit plans in existence which offer as an additional attraction, a partial coverage of the doctor's bills while the subscriber is in the hospital. It is too soon, perhaps, to judge of the practicability of this extra coverage but the result in a number of cases has not been all that the sponsors anticipated. The allowance for the doctor's bills is, in most instances, partial and inadequate but the patient upon receiving a larger bill, has objected strenuously and refused to pay. Naturally, he believed that he had purchased complete protection against his bill.

Minnesota Hospital Service is in a far better position because it has hesitated to offer any coverage that fringes upon insurance for medical services.

"WHY THE MEDICAL ADVISORY COMMITTEE"

[Monthly Editorial Prepared by the Medical Advisory Committee]

Recently, the chairman of The Medical Advisory Committee was asked: What is the function of The Medical Advisory Committee?

In the constitution and by-laws of the Minnesota State Medical Association adopted May, 1937, it is stated that: "Its function shall be to investigate and disseminate knowledge as to the cause of malpractice."

It is, therefore, a fact finding committee as well as a correlator and dispenser of the information gained through investigations. It is in no way an insurer against malpractice, pays no indemnities and gives no legal advice.

As has been said, experience is a good and probably the best teacher. So it has been with your committee. The general knowledge of cause and cure of the malpractice menace gained by the committee in the last several years should and will be of inestimable value to the Association and its members in the solidifying of the membership behind its objectives, and concretely showing a result in lessened premiums paid by the members for protection.

Continued observation of the general attitude of the membership shows a coöperative spirit which we believe is probably more noticeable than in any other profession, a growing criterion of good brotherhood.

Your committee believes that common sense is an indispensable part of its work; that a clear analysis of various problems as they arise is proper and just; that there are two sides to every case; that the great majority of the membership of our Association are honest with their clientele; that most members of the Bar Association would not bring an action against our profession if they were given the true facts in a case by the plaintiff; and that a miscarriage of justice in the courts of our state in this type of a case is at a minimum. Study shows it to be a fact that those things of common interest to us all are much more important and essential than our differences.

B. J. B.

TAKE YOUR CHOICE

There are interesting discrepancies between the book on Soviet medicine by Medical Historian Henry E. Sigerist of Johns Hopkins and the account of personal experience with Soviet medicine published a few years ago by one-time communist newspaper correspondent, Eugene Lyons.

Say Dr. Sigerist:

"Nobody can deny that Soviet medicine, in the short period of twenty years and under most trying circumstances, has stood the test and has created powerful measures for the protection of the people's health. It has demonstrated that socialism works in the medical field, too, and that it works well, even now, in the early beginnings of the social state. It is a system full of promise for the future—the very near future."

Says Mr. Lyons:

"We came, unluckily (through illness of Mrs. Lyons) to know a lot more about Soviet medical practice than most of our colleagues. Like the "stable" currency and the wonderful educational methods, socialized medicine under the official statistical surface was a snarl of contradictions, shortages and ineptness. Doctors and dentists regarded their obligatory work for the state as exaction and depended on private practice for their real income. The more famous medical specialists did not budge for less than 50 or 100 rubles; often it required pull to get their services at any price. The public health service was by all odds inferior to the free public and charitable health services available to the poor in cities like New York and Chicago. . . ."

"Ever after (Mrs. Lyons' experience in a Soviet hospital), the glowing reports of socialized medicine in Russia in American books and magazines have been a source of amusement to us. Always we have wished their authors only one punishment—a week or so as patients in the second-best hospital in Russia."

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

Minneapolis Physician Sentenced to 5 to 20 Years at Hard Labor Following Conviction for Manslaughter

Re State of Minnesota vs. R. J. C. Brown, M.B.

On November 25, 1939, Richard J. C. Brown, Negro physician of Minneapolis, was sentenced to a term of not less than 5 and not more than 20 years at hard labor in the State Prison at Stillwater, Minnesota, by the Honorable Arthur W. Selover, Judge of the District Court of Hennepin County, following Brown's conviction, on November 22, 1939, by a jury, of the crime of manslaughter in the first degree. Brown was arrested on August 16, 1939, by the Minneapolis Police Department on the complaint of the father of a 22-year-old Minneapolis girl, upon whom it was alleged that Brown had performed a criminal abortion on July 31, 1939. At that time, Brown was charged with the crime of abortion. However, the girl died at the Minneapolis General Hospital on August 23, 1939, and prior to her death she made a statement naming Brown as the one who had performed this criminal abortion. Subsequently, Brown was indicted on August 29, 1939, by the grand jury of Hennepin County along with one Martin Schmidt. The indictment charged them with manslaughter in the first degree. Both defendants entered pleas of not guilty and their bond was fixed in the sum of \$5,000.00 each. Brown's trial commenced in the District Court on November 16, 1939, and ended with the jury returning a verdict of guilty on November 22, 1939. Brown did not take the witness stand in his own behalf. The defendant Schmidt was named by the deceased girl as having recommended that she go to Brown, and as having furnished her with the \$25.00, which it is alleged was paid to Brown for his services.

The defendant Brown was born in Lincoln, Nebraska, January 17, 1893, and graduated from the University of Minnesota June 17, 1920, with the degree of Bachelor of Medicine. He was licensed in June, 1920, by the Minnesota State Board of Medical Examiners by examination. According to the records at the University of Minnesota, Brown never completed his internship and the degree of Doctor of Medicine was never conferred upon him. Judge Selover granted Brown a stay of execution of sentence until December 30, 1939, to permit the defendant to make a motion for a new trial.

A real campaign against tuberculosis demands a genuine investigation carried out with general practitioners looking for patients in the community, in industry and in home-making. We are finding an appreciable amount of tuberculosis through testing campaigns in schools but it is not one-quarter of what we would find if the campaign were extended to the groups where tuberculosis is more prevalent.—LONG, ESMOND R., Phila., Tuber. Conf., 1939.

OF GENERAL INTEREST

Dr. John Arthur Williams, who for the past four months has been associated with his uncle, Dr. L. A. Williams, in the practice of medicine in Slayton and vicinity, has accepted a position as surgeon in Gillette Hospital, Saint Paul.

* * *

Dr. John W. Johnson, son of Dr. and Mrs. Hans Johnson of Kerkhoven, who has just completed a year as resident physician at the Wyandotte General Hospital, Wyandotte, Michigan, has returned to Kerkhoven, where he will be associated with his father in general practice.

* * *

Dr. Milo H. Larson, formerly of Nicollet, is now located at Norwood, Minnesota.

* * *

Dr. L. R. Parson, formerly of Fergus Falls, is now practicing medicine in Elbow Lake, Minnesota.

* * *

Dr. Norman Sather, who recently completed a residency at Ancker Hospital, Saint Paul, has established offices in McIntosh, Minnesota, for the practice of medicine.

* * *

Dr. A. F. Adair has recently completed his residency in the Eye, Ear, Nose and Throat department at the Ancker Hospital, Saint Paul, and is now associated in the practice of this specialty with Dr. Carl L. Larsen, 1027 Lowry Medical Arts Building, Saint Paul.

* * *

Dr. William C. Bernstein of New Richland has sold his practice and will enter the Graduate School of Medicine at the University of Minnesota, where he will specialize in proctology.

Dr. Russell O. Spittler of Livingston, Montana, took over Dr. Bernstein's practice January 1. Dr. Spittler is a graduate of the University of Minnesota, 1932, and has practiced medicine and surgery at Livingston since 1933.

* * *

Dr. Richard Cranmer and Dr. Leo W. Fink of Minneapolis addressed the Scott-Carver Medical Society at New Prague December 12. They spoke on "Acute Conditions of the Abdomen" and "The Important Functions of the Nose," respectively.

* * *

Dr. Frank E. Burch, Saint Paul, sailed December 15 from San Francisco for Peiping, China, where he will spend four months as visiting professor of Peiping Union Medical College. He is being sent to China under the auspices of the Rockefeller Foundation. Mrs. Burch accompanied him.

In Memoriam

Charles E. Fawcett

(1869-1939)

Dr. Charles E. Fawcett of Stewartville, Minnesota, passed away at his home Friday, December 8, 1939, at the age of seventy.

Born in Marion, Minnesota, October 13, 1869, Dr. Fawcett attended rural schools and later went to Winona normal school and to Darling's business college in Rochester. After teaching several years he decided to study medicine and he completed his course at Northwestern University in Chicago in 1893.

Upon receiving his M.D. degree, Dr. Fawcett began practice in Austin, Minnesota, but after three months, he moved to Stewartville and practiced there continuously until his death.

On November 28, 1894, Dr. Fawcett married Myrta A. Phelps. Three daughters, Gale C., Lois M., and Frances, and one son, Donald N., were born of this union. Mrs. Fawcett died in 1910. In 1913, Dr. Fawcett married Mabel Bates Slater.

Dr. Fawcett was active in his community. He gave much of his time toward bettering the local schools and is credited with having been responsible for the fine local school system.

He was an active Mason and was Worshipful Master of the local lodge for four years. He was also a member of the Modern Woodmen of America. Although beyond the draft age, Dr. Fawcett volunteered during the World War and served as Captain in the Infirmary at Alexandria, Louisiana. A charter member of the Ivan Stringer post of the American Legion, Dr. Fawcett served for many years as Chaplain, the post he held at the time of his death. It was fitting, therefore, that the Captain be given a full military funeral at Woodlawn Cemetery.

A Methodist from childhood, Dr. Fawcett transferred his membership from the Marion church and served on the Church Board for forty-four years at Stewartville.

Since 1907, Dr. Fawcett had been president of the National Bank at Stewartville, where his keen knowledge of financial affairs served his community well. Six years ago tribute was tendered him for this phase of his community activity by men and women of Stewartville.

Dr. Fawcett had long been a member of the Olmsted-Houston-Fillmore-Dodge County Society, and the Minnesota State and American Medical Associations.

I used to wonder why people should be so fond of the company of their physician 'til I recollected that he is the only person with whom one dares to talk continually of oneself, without interruption, contradiction or censure.—HANNAH MORE.

PERFORATION OF MECKEL'S DIVERTICULUM BY FISH BONE

(Continued from Page 44)

through the present opening so this was closed and a right rectus incision was made. A Meckel's diverticulum about 2.5 inches long, then came into view, a little more than 1 inch in width at the widest point and at the base about 0.5 inch. In sponging out the fluid the gauze sponge caught on something sharp and with the aid of an artery forceps this sharp foreign body was pulled out of the side of the appendage about one-half inch from the tip. This proved to be a fish bone about an inch in length. The diverticulum was tied off and removed, the stump inverted and covered over as in the usual appendectomy operation. Drains were put into the pelvis and after a few stormy days following the operation the patient made an uneventful recovery, and in five weeks was back on his rural mail delivery job.

In questioning the patient he said that he not eaten any fish since last February or the first part of March and the fish bone must have been in the diverticulum at least since this time.

Summary and Conclusions

1. A short anatomical description of the anomaly of a Meckel's diverticulum has been given.

2. The patient had had typical symptoms of appendicitis ever since he was fourteen years old, but undoubtedly had a recurrent diverticulitis until a fish bone found its way into the diverticulum and burrowed its way through the various coats.

3. The fish bone must have been lodged in the diverticulum for at least six or eight weeks and during that time he had had no symptoms of it until the typical pain which he had had so many times during the past forty-eight years recurred with increased severity.

4. Although the incidence of Meckel's diverticulum is 2 per cent, and the percentage of those which cause trouble is very small, it is well to keep this condition in mind especially in cases in which there is a long history of repeated symptoms resembling those of appendicitis. Furthermore if such cases come to operation and the appendix is found not to be sufficiently diseased to explain the symptoms, exploration should be performed in order to eliminate the presence of a Meckel's diverticulum.

5. A fish bone perforation of a Meckel's diverticulum is rare; at least I have not been able to find the history of such a case in medical literature.

The State of Massachusetts has recently passed legislation which makes it possible to protect its citizens in medical affairs. Hitherto there has been no provision for examining candidates for licenses to practice medicine except by a written test—a method of determining competence considered inadequate by all other states. Now Massachusetts is requiring that those who take the licensing examination must be graduated from approved medical schools.

A board, which has the authority to formulate standards in medical education, has been organized and will pass on the qualifications of schools of medicine. Massachusetts is to be congratulated upon this step which raises the qualifications of its medical practitioners to the general level prevailing throughout the United States.—Editorial, Jour. A.M.A.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR JANUARY

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis (810 kilocycles or 370.2 meters), and Station WLB, University of Minnesota (760 kilocycles or 395 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month will be as follows:

January 6—Diphtheria and Smallpox.

January 13—Whooping Cough and Scarlet Fever.

January 20—Measles and Chickenpox.

January 27—Orthodontia.

NOTE: The last talk each month is sponsored by the Minnesota State Dental Association.

STATE MEETING

A new program plan will be followed for the next Annual Meeting of the Minnesota State Medical Association, 87th in the history of the association, which will be held at the new Mayo Civic Auditorium at Rochester, April 22, 23 and 24.

A group of special subjects has been chosen for the Tuesday and Wednesday programs and three or four speakers will be invited to talk on various aspects of each one. Among the subjects to be discussed from various points of view are Pre-Operative and Post-Operative Care; Coronary Disease; Cancer of the Breast; Progressive Loss of Vision; Fractures.

Monday's program will be given over entirely to members of the Mayo Clinic and at the conclusion of the day's proceedings there will be an open house with the clinic members as hosts in the Auditorium Arena. Exhibits will be open on this occasion and entertainment and refreshments provided.

Among distinguished out-of-state speakers who have already accepted invitations to speak are Drs. Harry E. Mock and Fred L. Adair of Chicago; and Dr. John O. Bower of Philadelphia.

The round table luncheons which proved a popular feature of the Minneapolis meeting will be continued this year with ten luncheons scheduled for each day of the meeting in Rochester hotels and dining rooms. Tours will also be arranged during the three days in groups of twenty for those who want to visit the Institute of Research. The annual banquet will be held at the Rochester State Hospital, Tuesday evening.

Special entertainment will be provided also for the Women's Auxiliary of the association, which will hold its annual gathering during the three days of the meeting. All wives of physicians will be invited to these functions.

WASHINGTON COUNTY SOCIETY

The Washington County Medical Society held its annual meeting on Tuesday, December 12. The following officers were elected by acclamation: President, D. Kalinoff; first vice president, Ray G. Johnson; second vice president, George McC. Ruggles; secretary-treasurer, E. Sydney Boleyn; delegate, E. Sydney Boleyn; alternate, Wade R. Humphrey.

Dr. Everett K. Geer of Saint Paul and Pokegama interpreted thirty-three chest radiographs from positive Mantoux reactors at the Stillwater High School. No lesions were demonstrable. Dr. Geer opined that positive reactors to the Mantoux test showing no demonstrable lung lesions should be referred to the family physician for very thorough general examination as tuberculosis may be present in some other part of the body. He cited several cases which proved such procedure would be very desirable.

MIDWESTERN FORUM ON ALLERGY

The second annual conference of the Midwestern Forum on Allergy will be held at the Palmer House, Chicago, Saturday and Sunday, January 13 and 14, 1940.

The meeting opens Saturday evening, January 13, with the annual get-together at 7 P. M. Saturday evening, Sunday morning and Sunday afternoon will be devoted to the scientific program covering numerous phases of allergy.

The profession of Minnesota is cordially invited to attend.

E. STARR JUDD LECTURE

Dr. Edward D. Churchill of Boston, Massachusetts, John Homans, Professor of Surgery at the Harvard Medical School, and Chief of the West Surgical Service at the Massachusetts General Hospital, will give the seventh E. Starr Judd lecture at the University of Minnesota in the Medical Science Amphitheater on Thursday, March 14, 1940, at 8:15 P. M. The subject of Dr. Churchill's lecture is "Surgery of the Lungs."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in surgery a few years before his death.

MINNESOTA RADIOLOGICAL SOCIETY

The fall meeting of the Minnesota Radiological Society was held in Rochester, Minnesota, December 2, 1939. The scientific program was given at the Assembly Room of the Mayo Clinic in the afternoon. Following dinner at the Hotel Kahler, the members were addressed by Dr. H. M. Worth on the subject "Radiology in England," and Dr. Shao-hsun Wang on "The Practice of Medicine in China."

TRANSACTIONS OF THE MINNEAPOLIS SURGICAL SOCIETY

Stated Meeting, Thursday, October 5, 1939

President, Dr. Willard White, in the Chair

Secretary: Dr. Harvey Nelson

CHRONIC DUODENAL STASIS

ARTHUR METZ, M.D.
Chicago, Illinois.

Chronic duodenal stasis is a condition characterized by the delay in passage of food through the duodenum. It has long been recognized but the condition is frequently overlooked in routine examinations. During the past twenty years, articles have appeared from time to time describing the condition and treatment outlined.

Etiology.—The etiology of duodenal stasis may be due to either a congenital anomaly with a resulting pressure on the duodenum where it passes over the spine, causing an incomplete obstruction, or it may be secondary to some mechanical obstruction such as tumor growths or adhesions.

The most common cause of stasis in our experience has been pressure on the duodenum where it passes over the spine by the mesentery attachment. It is usually associated with a ptosis of the abdominal viscera. In all of our cases we could account for the symptoms as being directly due to this cause.

Devine has described a type of duodenal stasis which he considers due to an abnormal action of the sympathetic nerves, for which he has devised a special operation consisting of a resection of a portion of the stomach.

Acquired obstruction secondary to tumor growths or adhesions or kinks can produce similar clinical findings.

It is difficult to estimate the frequency of chronic duodenal stasis secondary to congenital anomalies, for unless the clinician and roentgenologist make a careful search, many of the milder cases are overlooked. It has been estimated that about one-half of one per cent of all routine gastro-intestinal examinations in the x-ray department will show evidence of duodenal stasis.

Discussion of this paper will be limited to thirteen operative cases where the obstruction was found to be due to pressure on the duodenum by the mesentery attachment.

The age of the patients in this group was from fourteen to sixty years, the average being thirty-one. There were six males and seven females, all of whom were of the slender, undernourished type.

Symptoms.—The symptoms of duodenal stasis depend upon the degree of obstruction. When the obstruction is slight, symptoms vary from time to time and consist chiefly of recurrent attacks of nausea associated with a loss of weight and inability to carry on usual activities secondary to weakness occasioned by restriction of food.

In the more advanced cases, there is, in addition to the attacks of nausea, vomiting and a fullness in the right upper abdomen, which comes on immediately after starting to eat. The patient as a rule does not describe the sensation as pain but complains of a fullness which develops in the right upper abdomen soon after starting to eat, associated with the loss of appetite and inability to continue eating. These symptoms may become so pronounced during the first five or ten minutes that the patient is forced to end the meal for fear of vomiting. Pain may be present and inasmuch as it is localized in the right upper abdomen may suggest the presence of a gallbladder attack, but on examination there will be an absence of definite tenderness and rigidity which is characteristic of gallbladder disease.

In the more advanced cases the symptoms as above described increase in severity, so that the patient will avoid food, as there is the repeated feeling of nausea and vomiting when taking small amounts. In some cases the patient will attempt to eat frequent small meals so as to avoid distressing symptoms of repeated vomiting attacks.

Inasmuch as the patient shows no evidence of temperature, and blood and other laboratory findings are negative, the condition is sometimes looked upon as an hysterical vomiting, and as result the patient may receive very little sympathy or attention. This was true of one case that came under our care of a young boy, fourteen years old, where the attending physicians along with the parents had labeled the patient's symptoms as hysterical in character although the patient was extremely emaciated and exhausted before his true condition was recognized.

The diagnosis of chronic duodenal stasis is made by the history of recurring attacks of vomiting, which vary with the degree of obstruction, with the absence of other clinical findings suggesting an inflammatory lesion in the upper abdomen.

A positive diagnosis has to be made by careful fluoroscopic examination. The stomach will be observed as a long, vertical, J-shaped type, with a low placed outlet, and on watching the barium pass through the outlet, it will be found to remain in the duodenum to the right of the spine. The most striking finding is that of a duodenal shadow which is two to three times its usual diameter, and vigorous peristaltic waves are observed. The peristaltic waves may even assume the reverse type and the barium can be observed to return into the stomach. In some cases the barium will pass to the left of the spine after the peristaltic waves have been observed for five to ten minutes. The patient can definitely locate the area of fullness in the right upper abdomen at a point over the distended

duodenum and may even complain of the discomfort as that of a definite pain.

From fluoroscopic examination alone, duodenal stasis can be roughly placed into one of three classes:

1. Where there is a slight delay in barium passing through the duodenum, and after a minute or two it will pass to the left of the spine and the stomach will continue to empty itself.

2. Where there is a definite dilatation of the duodenum to at least twice its normal diameter and a delay of barium may be of five to ten minutes duration with evidence of reversed peristalsis associated with nausea and vomiting at the time of examination.

3. Where the obstruction is practically complete and dilatation is greater with pronounced regurgitation and vomiting and the patient shows marked emaciation. It is in this third group that prompt surgical treatment is indicated.

Differential diagnosis will have to be made from chronic gallbladder disease, duodenal ulcer and also from other anomalies such as diverticuli and cysts in the right upper abdomen, which should be easily eliminated by two or three repeated fluoroscopic examinations.

Treatment.—The treatment depends upon the degree of obstruction present. In the first stage where obstruction is only slight and the symptoms come and go, careful medical management by regulating the intake of food associated with rest at meal-time will frequently produce the desired results. The object of the treatment is to increase the weight of the patient so as to increase the amount of fat in the abdomen with the hope that the pressure on the duodenum will be reduced and in this way relieve the mechanical narrowing of the lumen.

In the second stage where the symptoms of fullness associated with nausea and vomiting are persistent, the patient should be kept in bed and given frequent feedings of nourishing food. Various positions should be tried during and after eating with the hope of relieving pressure and aid in the passing of food over the spine. Sometimes lying on the left side or with face downward will give relief and even the knee-chest position has in some cases given very satisfactory temporary results.

If the patient does not make satisfactory progress in one or two months after careful medical management, surgical treatment is indicated.

In the third stage where there is a high-grade obstruction due to pressure, a course of medical management might be tried, but with pronounced symptoms of vomiting and loss of weight the patient should be given prompt relief by surgical treatment.

Surgical Treatment.—The most common surgical treatment recommended for chronic duodenal stasis is duodenojejunostomy. This operation when properly performed will give very good results. In making the enterostomy, care should be observed to make the opening large so as to give prompt emptying of the distended duodenum.

The duodenum to the right of the spine is located

retroperitoneal, which places it deep in the abdomen and makes the operation difficult, as extra dissection is required to mobilize the intestines enough to do an enterostomy.

A second surgical procedure can be considered in giving relief which consists of a regular posterior gastroenterostomy accompanied by the placing of a silk ligature firmly about the pylorus. In these patients where the stomach is large, a posterior gastroenterostomy is much easier to perform than a duodenojejunostomy. The placing of a heavy silk ligature about the pylorus, tying it just tight enough to obstruct the lumen and not tight enough to produce a necrosis, will prevent gastric contents from entering the duodenum, thus making the food enter the duodenum to the left of the spine, after which it has no obstruction to its course through the intestinal canal. In our experience this has been a very satisfactory surgical procedure.

In our series of thirteen cases, ten were relieved by the use of gastroenterostomies and placing of silk ligature about the outlet. All ten patients made uneventful and good recoveries and have been able to continue their normal activities.

The first and the most severe case was a patient, fourteen years of age, who was operated upon twelve years ago. He was almost moribund at the time due to dehydration, so that he was a poor surgical risk. Owing to his weak condition, it was decided to do the simplest operation possible in order to get food into his small intestines. To accomplish this it was decided to do a gastroenterostomy and tie off the pylorus, as this seemed easier to do than a duodenojejunostomy.

Inasmuch as this patient made a very prompt and good recovery, it was decided to use a similar operative procedure on subsequent cases as they occurred, averaging about one a year. This accounts for the large proportion of gastroenterostomies as compared with duodenojejunostomies.

The most recent case was a duodenojejunostomy where a generous opening was made and the patient made a good clinical recovery.

Our first operative experience with this condition dates back to 1927 where a patient was diagnosed acute duodenal regurgitation in which a duodenojejunostomy was done but apparently in this patient the opening was not large enough so that although the patient got some relief, she never was completely well.

A second patient a year later was operated upon, at which time a duodenojejunostomy was performed and apparently in this patient the opening was not large enough, as the symptoms persisted. The patient was operated upon a second time and a gastroenterostomy was performed, the pylorus being ligated. This gave the patient better results, but here again after the second operation the patient never got entirely well as she was constantly complaining of fullness and occasional vomiting and regurgitation of food. When the patient was observed under the fluoroscope, the barium passed out of the stomach into the small intestines through the gastroenterostomy opening and was observed to go in both directions. In order to keep

barium out of the proximal loop, it was decided to do a third operation which consisted of placing a silk ligature just proximal to the gastroenterostomy opening. In this way all food was kept out of the duodenum for she then had a silk ligature at the pylorus and one proximal to the gastroenterostomy. The duodenum was then used only as a duct for the bile which mixed with the food stream through the former duojejunostomy opening.

At the time of the third operation, an opportunity was had to inspect the silk ligature that had been placed about the pylorus some seven months previous and it was found to be in good condition and walled off.

We have a series of fifty-one patients in which the pylorus has been ligated with silk for either duodenal regurgitation or duodenal ulcer and in no case have we had any evidence of bad effect.

Our operative experience on fifteen cases of duodenal regurgitation during the past twelve years has recalled to our mind at least two cases that were not recognized some twenty to twenty-two years ago. One of our prominent clinicians used to repeatedly state "how nice it would be if our foresight could be as good as our hindsight." We can recall two young women who were under the care of two of our leading clinicians with a pernicious type of vomiting and at that time we were unable to locate the cause. As a result of our later experience, beginning twelve years ago, in recognizing a duodenal regurgitation, it is evident that if the first two cases had been recognized, surgical treatment could have been employed and relief obtained. Both patients had been fed for months through a duodenal tube but gradually progressed to exhaustion and death.

Conclusions.—It is important to recognize the condition of chronic duodenal stasis which is characterized by recurring attacks of vomiting associated with loss of weight and that the diagnosis depends essentially on a careful fluoroscopic examination. It is important that the roentgenologist always be on the alert to follow the barium through the duodenum and be on the lookout for a dilated duodenum and peristaltic waves with delay of the passing of barium through the duodenum.

When the condition is recognized and it is not too advanced, medical management should first be used, but if satisfactory results are not obtained, surgical treatment should be resorted to.

The surgical treatment is optional and may consist in either a duojejunostomy, making sure that the enterostomy is made large, or a posterior gastroenterostomy and tying a silk ligature about the pylorus just tight enough to obstruct the lumen and not tight enough to produce a necrosis.

Motion pictures of an African big game hunt were shown by Dr. Metz, who had been a member of the hunting party which took a trip to the Tanganyika Territory in Africa. The pictures were taken by a professional photographer.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

DIAGNOSIS AND TREATMENT OF DISEASES OF THE ESOPHAGUS. Porter P. Vinson, B.S., M.A., M.D., D.Sc., F.A.C.P. Professor of Bronchoscopia, Esophagoscopy and Gastroscopy, Medical College of Virginia. 224 pages. Illus. Price, \$4.00, cloth. Springfield, Ill.: Charles C. Thomas, 1940.

AN INTRODUCTION TO MEDICAL MYCOLOGY. George M. Lewis, M.D., and Mary E. Hopper, M.S. 315 pages. Illus. Price, \$5.50. Chicago: Year Book Publishers, 1939.

This monograph of approximately 300 pages, should be of great interest to both practitioners and students. The subject matter is handled deftly and completely, yet brevity is the keynote throughout the entire work so that reading is not tiresome. There is ample practical information concerning the diagnosis and therapy of the various mycoses, discussions pertaining to immunity and sensitization to the fungi, as well as sections devoted to their microscopic and cultural characteristics. The book is printed on high grade paper, the type is unusually good, and the numerous photographs are excellent. In my opinion, it is a worthwhile text and can be highly recommended.—CARL W. LAYMON, M.D.

ACCEPTED FOODS, AND THEIR NUTRITIONAL SIGNIFICANCE, a publication of the Council on Foods of the American Medical Association. Cloth, Price, \$2.00 postpaid. Pp. 512. Chicago: American Medical Association, 1939.

Accepted Foods, and Their Nutritional Significance contains descriptions and detailed information regarding the chemical composition of more than 3,800 accepted products, together with a discussion of the nutritional significance of each class of foods. The book provides also the Council's opinion on many topics in nutrition, dietetics and the proper advertising of foods.

This book will be a welcome reference book for all persons interested in securing authoritative information about foods, especially the processed and fabricated foods which are widely advertised. The accepted products are classified in various categories; fats and oils; fruit juices including tomato juice; canned and dried fruit products; grain products; preparations used in the feeding of infants; meats, fish and sea foods; milk and milk products other than butter; foods for special dietetic purposes; sugars and syrups; vegetables and mushrooms; and unclassified and miscellaneous foods, including gelatin, iodized salt, coffee, tea, chocolate, cocoa, chocolate flavored beverage bases, flavoring extracts, dessert products, baking powder, cream of tartar, baking soda, cottonseed flour. There is a suitable subject index as well as an index of all the manufacturers and distributors of food products that stand accepted by the Council on Foods.

Accepted Foods is indispensable for the library of every physician concerned with foods and nutrition.

ENDOCRINE GYNECOLOGY. E. C. Hamblen, B.S., M.D., F.A.C.S. 453 pages. Illus. \$4.95. Springfield, Ill.: Charles C. Thomas, 1939

Dr. Collip, in his foreword, pays Dr. Hamblen a very deserving thank you for his admirable handling of this work prepared for the general practitioner.

The author's preface states his original purpose in collecting the material presented in his monograph was the organization of a series of lectures on endocrine gynecology for his classes of medical students, but their kind reception of his efforts prompted the preparation of these lectures for publication.

The author's expressed hope that the physician doing general practice, who does not have the time to review the various reports on endocrine subjects as they appear in the many diverse journals and yet who is interested keenly in the endocrine physiology and pathology of women, will find this volume helpful has been magnificently granted.

The pharmacology and chemistry sections of the sex-endocrine principles will be welcome to the reader. The illustrative material, hand drawn and otherwise presented, is truly a work of art.

You will all welcome this first edition, so characteristic of the Charles C. Thomas books and of Duke University School of Medicine productions. It is the expressed wish of the reviewer that the author will present revisions as often as new material is timely. The book is a treasury of references and a storehouse of

information, clearly and understandingly presented for the general practitioner, gynecologist and pediatrician.—LILLIAN L. NYE, M.D.

VARICOSE VEINS, Alton M. Ochsner, M.D., and Howard Mahorner, M.D. 147 pp. Illus. Price, \$3.00. St. Louis: C. V. Mosby Company, 1939.

This book although of only 147 pages, including the references and index, is of nice width and breadth, measuring 7x10 inches. It is well bound, and the printing and the illustrations are excellent.

The book is dedicated to Rudolph Matas and the Foreword is written by Doctor Matas. It is made up of ten chapters, including the history, anatomy, pathology, physiology, etiology, clinical aspects, examination of the varicose vein patient, the treatment, and the final chapter devoted to treatment of varicose ulcers.

The history of the treatment of varicose veins is well written and is interesting. The chapters on anatomy, pathology, physiology and etiology are what one might expect. The chapter on the examination of the varicose vein patient consists largely of the various tests for evaluating the circulation in the venous system of the lower extremities. The comparative tourniquet test devised by the authors is particularly stressed. Under the chapter entitled "Treatment," the injection treatment and the operative treatment are fully de-

SILVER PICRATE *Wyeth's*

has shown a

CONVINCING RECORD OF EFFECTIVENESS in ACUTE ANTERIOR URETHRITIS

due to Neisseria gonorrhoeae

scribed, especially the latter, which to my mind is the most important.

Altogether the book is a very desirable one to have for any one interested particularly in this subject.

M. G. GILLESPIE, M.D.

ANNUAL REPRINT OF THE REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR 1938. Cloth. Price, \$1.00. Pp. 120. Chicago: American Medical Association, 1939.

This volume as usual contains noteworthy examples of the various kinds of reports made by the Council on Pharmacy and Chemistry: (1) preliminary reports; (2) supplemental reports on therapeutic or pharmacologic problems; (3) reports on the rejection of preparations offered for the Council's consideration.

Among the preliminary reports in this volume that on Sulfapyridine, which carries a special article by Dr. A. Perrin H. Long, a Council member who has been much concerned with the work on this drug, is perhaps of greatest interest. After the Food and Drug Administration had released the drug for the use of physicians early in 1939, the Council accepted various brands for inclusion in N.N.R. and in connection with the published descriptions issued another status report (J.A.M.A. 112:1830, May 6, 1939) based on a questionnaire sent to men who had been prominent in the experimental use of the drug. This report, no doubt, will appear in the next volume of reprinted Council reports. Other preliminary reports are the following: Allantoin, a preparation of glyoxyldiureid purposed to supersede the use of surgical maggots; and Sulfapyridine, published shortly before the Council acceptance of this new chemotherapeutic drug.

Among the supplemental (or status) reports are those on Colloidal Sulfur in the Treatment of Chronic Arthritis, showing that much confirmatory evidence is needed to establish the value of this therapy; on Ergonovine, a careful study of the relation of this newly discovered principle to ergot therapy in general; and on PicROTOXIN in Poisoning by the Barbiturates, showing the promise and the present limitations of this antidotal therapy.

Among the reports of rejection the following are noteworthy: Collodaurum, a "colloidal gold" preparation, promoted with unwarranted, exaggerated and misleading claims for its use in the treatment of cancer; Dermo-G, stated to be a mixture of Spermaceti, White Wax, Oil of Sweet Almonds, Sodium Borate, Precipitated Sulphur and Water, an unscientific and superfluous mixture marketed under a therapeutically suggestive name with exaggerated, unwarranted claims; Fru-T-Lax, a needlessly complex and unscientific mixture advertised to the public under a misleading and inadequately descriptive name with claims which are unwarranted; and Hyposols Sulisocol, claimed to be

"Sulphur Colloid" in 2 cc. of "Autoisotonized Solution," exploited for use in arthritis with inadequate evidence to its therapeutic value. Other rejections are explained in the reports on Map and Myoston, Nupercainal—"Ciba," Pulvoids Sulfanilamide and Sodium bicarbonate (The Drug Products Co., Inc.), Quinoliv, Sedormid, and Tri-Costivin.

TEXTBOOK OF NERVOUS DISEASES. Robert Bing, Professor of Neurology, University of Basel, Switzerland. Translated by Webb Haymaker, Asst. Clinical Professor of Neurology, University of California. 838 pages. Illus. Price, \$10.00. St. Louis: C. V. Mosby Co., 1939.

After an examination of this book, the reviewer is much impressed by the imposing structure of modern neurology which is here set forth. The author succeeds admirably in condensing a massive amount of material, and his attempt "at the exposition and interpretation of facts rather than of devious hypotheses," a feat briefly and modestly indicated in his foreword to the American Edition, will indeed "be found profitable." The latest advances in neurology in Europe and America are clearly and concisely presented; where there is more than one opinion on important matters, the conflicting opinions are presented with sufficient collateral evidence to enable the reader to form an intelligent judgment. The style is lucid and there is never any doubt as to what the author intended the reader to understand. This book should be of great value to the medical student as as source of information for his daily studies, and to the busy doctor as a convenient, concise and complete reference for aid in the solution of his clinical problems.

BENJ. F. DAVIS, M.D.

A TOPOGRAPHIC ATLAS FOR X-RAY THERAPY. Ira I. Kaplan, B.S., M.D., and Sidney Rubinfeld, B.S., M.D. Price \$4.00. Chicago: Year Book Publishers, Inc., 1939.

The authors have provided the profession with an atlas which is most practical in its application. It is their answer to the general lack of precise knowledge as to the proper setting of patients for the administration of x-ray therapy. There are fifty-five full page plates showing the anatomy of the internal organs from the head down through the perineum. Since a correct knowledge of anatomy is needed in proper treatment, the location of the organs of the body was arrived at by using an average based on data obtained from standard works on anatomy and from clinical, surgical and autopsy material. Each plate shows the visible anatomic landmarks, palpable internal landmarks, the internal parts to be irradiated, and the exact placement of the treatment cone.

This atlas is a valuable adjunct to those practicing x-ray therapy. It is most handy and useful as a reference and guide to proper localization of the x-ray beam. It is not intended to supplant the more extensive books which deal with cross section and topographic anatomy.

SOME OBSERVATIONS ON BOEHLER'S TREATMENT OF FRACTURES*

B. S. ADAMS, M.D.

Hibbing, Minnesota

A YEAR and a half ago, I spent a month in Vienna, going there chiefly to observe the traumatic work of Professor Lorenz Boehler. I was especially interested in his methods of treating fractures of the vertebræ.

All of Boehler's work on fractures is based on his three cardinal principles: reduction, immobilization, and exercise of all joints not immobilized. Some have criticised Boehler for being over methodical, for using exactly the same treatment in every fracture, for not considering the differences in build, temperament, severity of injury, or any of the numerous other factors pertaining to the particular case, contending that he is working with a people so different from ours that the methods used by him would never do in this country. Boehler is a very systematic man. He has worked out a definite method for every kind of fracture and follows that quite closely; even the number of plaster bandages for each fracture is definitely in his plans. And he does follow his own method quite closely because he has found by much experience that his methods do work and that he gets good results with them. But if there are objections in any particular case to his usual method he will change to meet conditions as they exist, and when he finds that his usual method or plan can be improved he accepts the new. If a certain method is found to be giving unsatisfactory results he studies and ponders the problem until he devises a better plan. Boehler has a keen mind and a studious temperament and seems to be constantly watching his results, ever watchful for something better if what he is already using is

not giving the results he wants. In his work, Boehler is rather conservative, is usually deliberate, yet when occasion demands, he can operate rapidly and very skillfully. He does not seem to hurry but every movement seems planned and for some definite purpose; the same is true in his talking. Boehler speaks beautiful English, never using a needless word, but always choosing words that are very expressive and which definitely convey the idea he wishes to express. He is very kind to his patients and they seem fairly to worship him. He has the respect of his assistants; and the nurses and orderlies seem to have the highest regard for him. Yet he can be quite sharp and sarcastic at times.

When operating he does not remove his ordinary trousers or his white shirt that he always wears; he scrubs for operations very carefully, wears a face mask but no cap (he is entirely bald); he wears a sterile gown and rubber gloves and is meticulously careful in his technic; he always has a group of visiting surgeons around his table as closely as they can crowd and he seems to take pride in this, saying that he has never had any infection from this cause, rather deriding some Parisian and other centers where visitors have to watch from outside a windowed partition. Boehler does not believe in chemical disinfectants, very seldom uses iodine or other chemicals except soap and water, benzine and perhaps ether. His assistants often use iodine but quite sparingly; merthiolate and other disinfectants are too expensive for European clinics. He says he seldom has any infections following his operations, and I did not see any while I was there. In closing his wounds he

*Read at the annual meeting of the Northern Minnesota Medical Association, Detroit Lakes, Minnesota, September 8, 1939.

almost always introduces, through a separate incision, a rubber drain tube which he removes in twenty-four hours. He is, however, very careful to stop all bleeding before closing an incision, as he says most wound infections are due to bleeding. In compound fractures, he says the skin wound is much more important than the bone injury. All wounds from injuries, trivial or severe, are thoroughly debrided, sutured with silk, and a rubber drain inserted, and complete rest required. For infections, his treatment is rest and elevation. He does not believe heat is of any particular value and seldom uses heat.

Three Cardinal Principles

Let us consider his three cardinal principles:

Reduction.—Boehler holds that the most important factor in reduction is to obtain good alignment without rotation. Alignment must be as perfect as possible and if 5 per cent or more out of alignment the bone is not reduced. He judges alignment by the center of the shaft. The fracture should be end to end, need not be exactly fitting, and if offset, it is of minor importance, but the alignment must be perfect. Shortening must be reduced to the minimum, and not over 1 cm. is allowable. Good alignment, end-to-end position, no angulation or rotation, and no shortening make for good reduction.

Immobilization.—Boehler says that complete uninterrupted immobilization from the time the bone is reduced until strong bone union takes place is absolutely necessary. Failure to accomplish this causes non-union. He favors immobilizing the bone too long rather than for too short a time. He does not believe immobilization of a joint results in a stiff joint; rather he believes motion started too early in a fracture involving a joint causes stiffness. He wants immobilization until the bone is strongly united whether it takes eight or ten weeks, or, for example in a leg, four or five months. About the only exceptions to this are in fractures of the upper humerus without displacement, shoulder and humeral fractures in old people, and motion of the arm in clavicle fractures. Except when in bed with traction he uses plaster of Paris almost exclusively for immobilizing. I saw no crutches and no wooden or artificial splints.

Airplane splints, made by his assistants, are

commonly used for fractures of the arm and for all upper arm cases. He prefers these made in his own hospital by his assistants because they fit more snugly into the axilla. Possibly expense is another factor. In many of his upper arm fractures, he uses plaster with the airplane plus traction.

Exercise.—Exercise of all joints not fixed in plaster is a very important procedure in the Boehler clinic. This means vigorous exercise regularly and frequently done—fifty times a day or more. A visit to his out-patient department as well as watching his patients in the hospital, shows a well laid-out system carried out thoroughly and systematically.

Methods of Treatment

To tell all my observations in a short paper such as this would be impossible. I wish to bring out a few of the high-lights of his methods, especially the things that impressed me most, and go into some detail regarding his treatment of back fractures.

Anesthesia.—Local injection of 2 per cent novocaine still seems to be his favorite anesthetic for most fractures. In some cases it seemed to work beautifully, but in his Colles' fractures the patients appeared to suffer a good deal of pain. He used spinal anesthesia in reducing the os calcis but local in all others that I observed. For more extensive operations, as an old fracture involving much joint dissection, ether was used.

Colles' Fracture.—Reduction is effected by a long strap attached to a hook on the wall, looped around the upper arm just above the elbow for countertraction. His assistant grasps the patient's thumb with one hand, and the second, third, and fourth fingers with his other hand. The fifth finger is not included because it might cause bowing of the hand. Strong traction is continued for at least five minutes. Then he makes very strong flexion of the wrist often until the fingers touch the forearm. Strong pressure is maintained over the dorsum at the fracture site, the hand is kept flat, and a molded plaster of Paris splint is applied along the dorsum of the hand and forearm from the base of the fingers to just above the elbow and lying more to the

radial side and molded carefully. A wet gauze bandage is wrapped around this; next a film is taken. If reduction is satisfactory the wet bandage is removed lest shrinkage cause pressure, and a dry gauze bandage is applied. Next day a volar plaster bandage is applied from a little above the finger base to elbow and a circular plaster bandage is applied allowing free motion of elbow and fingers. Anesthesia is local. Splinting is maintained for four weeks. In Colles' fractures he measures the length as well as the angle, watches alignment, and makes certain that wrist motion is free before applying the cast. Fractures of the forearm are reduced in a similar manner, also making dorsal pressure on the distal fragment with volar pressure proximally, pressing until it feels as though over-corrected. A plaster molded splint is applied from the top of the shoulder along the upper arm and down the dorsum of forearm on the radial side. A volar splint is then applied from the thumb to the elbow, the elbow being flexed to a right angle, the forearm being placed in midposition unless the fracture is in the upper third of the radius when it is supinated. Two small rods are then placed against the plaster to help keep the two bones separate—the dorsal rod being just above the wrist and the volar higher. A circular plaster bandage is then applied from thumb to axilla. The cast is retained for eight weeks. If the fracture is badly displaced he may use two Steinman pins, the upper being placed through the olecranon process and the cast, the lower pin through the bones of the wrist or of the metacarpals and through the cast. In all fractures of the forearm, it is placed in midposition except in those of the upper third of the radius, in which it is held in supination. Fractures of the head of the radius are fixed in plaster for three weeks unless badly displaced, in which case the head is removed. An olecranon, if not displaced, is fixed in flexion for three weeks; if displaced, he uses wire and fixes in flexion.

Upper Arm Fractures.—For all humerus fractures except those of the head of the bone in old people he uses an airplane splint made of Cramer wire. With this he uses a plaster molded splint on the outer surface of the upper arm carried around the elbow and down the forearm. A volar plaster splint to the elbow is added if necessary. If the fracture is hard to correct,

he uses screw traction to reduce, applies plaster splints and maintains traction by a traction rod on the end of the airplane splint. The airplane must fit snugly into the axilla to avoid angulation of the fracture. He uses starch bandages to hold the airplane in place and sews all bandages and straps securely. For fractures of the head of the humerus with no displacement he uses no retention apparatus and allows free motion in a sling after three days.

Ankle and Leg Fractures.—All ankle fractures having no displacement are put in plaster immediately. In applying the cast, the patient is seated on a table with the leg flexed at the knee and hanging over the edge of the table. The foot is supported on the doctor's knee with the foot flexed. A plaster molded splint extending from the tip of the toes on the plantar surface of the foot is carried up the back of the leg to the top of the fibula and molded carefully after cutting for heel corners. Three circular plaster bandages are used, each starting at the top and continued down to the end of the toes, but cut away on the dorsal surface to allow full dorsiflexion of toes. The cast is maintained from four to six weeks. If the fracture is severe and displaced, with rupture of lateral ligaments, the cast is kept on from ten to twelve weeks. In fractures of both malleoli with eversion (usual type) he makes very strong pressure on the lateral side of the ankle and applies a cast which must be retained for ten weeks. If the ankle is inverted, reduction must be done very early and even then results are apt to be poor. If severe, screw traction may be needed. These are serious fractures. If a small piece only two or three mm. wide is broken off the posterior surface of the tibia, no special treatment may be needed, but if a large piece such as a third of the surface is broken off, he applies screw traction on a Braun frame. Boehler says a fracture of the upper end of the fibula accompanied by a slight fracture of the posterior distal end of the tibia with a torn internal ligament makes a serious fracture and requires a plaster cast for ten weeks. These are easy to miss. Fractures of the anterior surface of the distal end of the tibia, he places in a cast with the foot in plantar flexion for six to ten weeks. Fractures of the leg above the ankle, without much displacement, are put in a plaster cast extending up the thigh

with the knee flexed slightly. If badly displaced, he uses screw traction extension, followed by a cast, using a Steinman pin through the os calcis. The leg is then placed on a Braun frame with a two-kilo weight traction for four weeks. After that he removes the pin and applies a plaster cast with a walking heel.

Femur Fractures.—Boehler's first treatment for all fractures of the femur, regardless of location, is extension by means of a two millimeter Steinman pin through the upper end of the tibia. If traction is needed longer than three weeks, as in fractures of the shaft, the pin is removed from the tibia and inserted through the lower end of the femur. His reasons are that a pin through the lower end of the femur early may infect a hematoma in the thigh, traction of the tibia longer than three weeks may loosen the knee. With traction, he places the leg on a Braun frame. For a pertrochanteric fracture, he uses pin traction for three weeks followed by skin traction using Unna paste. Later he divides the traction weight equally between the thigh and the foot; he always uses one-seventh body weight for leg extension. If coxa valga develops from extension, he lessens the weight. He uses some abduction but does not stress this. Shaft fractures are in pin traction through the upper tibia for three weeks followed by pin traction through the lower femur. The same treatment is used for fractures above the condyle. In all of these the foot of the bed is elevated, a Braun frame is fastened to the end of the bed, a box placed for the good foot to brace against, and rotation is regulated by a cord from the end of the pin to the overhead rod. No knee motion is allowed while a pin is in the bone. After the union is strong, he removes traction, uses Unna paste from toes to groin, allows knee flexion and, when sufficiently strong, allows hip motion.

Fractures of the Vertebrae.—Of all Boehler's work, his methods and treatment of broken backs seemed the most outstanding and spectacular. The results he obtains are truly marvelous, especially in some cases with marked paralysis. His patients seemed so very comfortable in spite of huge and ungainly looking casts and exercise is started so early it is hard to believe they have suffered a serious injury. At the time I was there, Boehler had twelve or thirteen broken

backs in his hospital, several coming in while I was there and others leaving. All were walking and taking vigorous exercise except one who was permanently paralyzed, and who had not come to Boehler until two weeks after his accident. It was most interesting to watch the development in these cases during the four weeks I was able to observe them; first walking very carefully and feebly, gradually increasing exercises until they were able to take very vigorous movements and carry heavy weights on their heads. Boehler claims his patients come out of their casts with a stronger and more supple back than they had before the accident. Of fifty cases, he told me all were working and without compensation except one man who was over sixty years of age. That his cases are really fractures is proven by the films.

Hyperextension in a cast is the method used by Boehler in all cases. If any lateral displacement is present this must be reduced first. He does this by strong extension, one assistant pulling on the legs and another pulling against this on the head and shoulders; then manipulation at the site of the displacement to obtain reduction. Hyperextension must be marked and extreme and the patient held in a body cast from three to nine or ten months according to the severity and amount of displacement and compression. This should be done just as soon as the patient is brought in and if any paralysis is present it must be done at once as pressure on the nerves is the cause of paralysis in most of these cases. If this pressure is not quickly released permanent nerve injury follows and paralysis will be permanent. Boehler says the only hope of these paralyzed cases is immediate reduction by hyperextension. With hyperextension he expects a good result with freedom from paralysis in most of his cases, and even in cervical fractures in 50 per cent or more of the cases. His method is to suspend the patient's trunk on a strap four inches wide for a sufficiently long time to overcome the deformity and, if a compression fracture, for the compression to unfold or widen out. This may take from one to several hours and during this time repeated lateral films are taken to watch the results. The only anesthetic used is local with morphine, and in some not even local is used. It seemed a trying procedure for the patient, tiring, though not especially painful. Then a plaster of Paris body cast is applied from

the groin to the axilla. He uses ten plaster bandages each five meters long by twenty centimeters wide. Pads of felt are applied over the iliac crests and over the point of lordosis or fracture, and a stockinette is drawn over all, no other padding being used. Trimming after setting of the plaster consists of a small opening in back at the point of the lordosis, a large opening over the abdomen, axillary openings for free motion of the arms, and similarly in the groins for free and full extension and flexion of the thighs. Pressure is necessary at three points: in front at the top of the sternum, over the pubic bones, and behind at the point of fracture—a three point pressure. In applying the cast he gets more marked hyperextension if the patient lies on his back on the strap. All fractures of the dorsal spine are placed with the patient lying on his back. Ordinary lumbar fractures may be reduced with the patient prone, but if severe or complicated he must lie on his back. If the cast is to be applied with the patient lying on his abdomen, the suspending strap is placed under the chest at the armpits; if on the back, it is placed under the site of the fracture, the best place being under the twelfth dorsal vertebra.

The procedure in reducing and immobilizing fracture of the vertebra is as follows: The patient lies prone upon a table with sandbags under the ankles and under the thighs. The legs and thighs are strapped to the table and the patient lies so that the pubes are at the end of the table when the end is dropped. A four inch wide strap (webbing) is placed under the axillæ, which have been well padded, this suspending strap being enclosed in a long cellophane envelope so it can be pulled out after cast has been applied. The suspending strap is fastened to an iron rod about two feet long and this is raised by a rope through a pulley on the ceiling. The patient is raised by this, with arms extended above his head and resting on a table that is also raised. His body is now supported by his thighs on the table and the strap under the axillæ, allowing the trunk to sag. After waiting about an hour, if lateral films show the compression to be satisfactorily reduced, the body cast is applied from axilla to groin, ten plaster bandages being used and molded very carefully and applied very evenly, special care being taken to apply this cast snugly against the upper ster-

num, against the pubic bone, and in the back against the padded fracture site. After the cast is hard and strong, the patient is let down, the suspension strap is pulled out of its cellophane envelope (this is impossible without the cellophane), the strap openings are closed with plaster bandage and the cast is trimmed to allow full arm and thigh motion. An opening is made over the abdomen, and one in the back at the point of fracture. The patient is encouraged to get out of bed the next day and to start walking at once, or at least in a few days. Most of Boehler's patients were taking very vigorous bending exercises in less than a month. The procedure when the patient lies on his back is similar, the cellophane-enveloped strap being located under the site of the fracture.

Fractures of the Upper Dorsal and Cervical Vertebrae.—Extension is required in addition to hyperextension. The patient is put in hyperextension lying on his back with strap in the axillæ. A Gleason head strap is attached. One assistant does nothing but hold the head. A scale is attached to the arch holding the head with a pull of from 15 to 30 kilos, and the extension is made a little downward as well as longitudinally. The cast is applied, extending in fractures of the dorsal spine to the pubes. The cast for fracture of the cervical spine should extend to the lower end of the sternum, the higher fractures requiring the cast to be extended higher on the neck and head. A cervical spine fracture requires the extension of the cast up the neck onto the back of the head and up onto the chin with the head and neck hyperextended, the face being directed toward the ceiling.

In cases with paralysis, it is very important to reduce vertebral fractures immediately. Many cases of paralysis are due to pressure on the intervertebral nerves and not to the accident itself. In these, if reduction is done within a few hours, recovery will be complete, but if left and not reduced early, nerve injury will follow in a very short time from pressure on the nerves and the damage will be permanent.

Boehler starts his patients walking after fractures of the vertebrae as soon as possible. If there is no paralysis this is instituted in one to three days. Exercises are increased as rapidly as possible. Most patients take vigorous exer-

cises in about three weeks, such as bending, standing on one leg and swinging the other, full arm motions, and carrying weights on the head. In from two to three months, his patients are carrying from 30 to 40 kilo on their heads. One of Boehler's favorite exercises is for his patients when convalescing, but while still in casts in the hospital, to lie across the bed with the trunk and

cast part extending beyond the edge of the bed while the assistant holds the feet down on the bed. They then raise and lower the upper end of the body, which is extended beyond the bed, as fully as possible. This exercise is repeated daily. Boehler says his patients recover with a back stronger and more limber than it was before the accident.

TUMORS OF THE NEUROMYO-ARTERIAL GLOMUS*

F. T. BECKER, M.D.†

Duluth, Minnesota

GLOMUS tumors are of extreme interest because, notwithstanding their small and insignificant size, they are able to produce severe pain and agony to the afflicted patient. These growths vary from a pin head to hazel nut in size and are a benign hypertrophy of existing arterial-venous anastomoses. As these anastomoses are more frequent on the extremities, especially the fingers, and nail beds, the tumors are therefore more prevalent in these areas. They appear as slight bluish-red elevations on the skin and the most diagnostic feature is the agonizing pain which the patient feels on the slightest pressure. When these growths are subungual, they are not always visible. The diagnosis can only be made by the extreme pain manifested by pressure on the nail. Occasionally a slight bluish discoloration may be noticed under the nail, or if the tumor has been present for a sufficient time a roentgenogram of the finger may show some erosion of the phalanx. It is my purpose in this paper to describe two typical cases of this condition, and briefly review the normal physiology and histology of these tumors.

A Review of the Literature

There have been so many excellent reviews of this subject published in the American literature during the past few years that it is superfluous to give a detailed discussion. These peculiar tumors have been described by numerous authors³ during the past fifty years under various names

such as "angiosarcoma," and "painful subcutaneous tubercles." It remained, however, for Barré² to clearly outline the clinical manifestations and to establish that surgical excision was curative. These specimens were studied by Masson,⁹ who described their histologic characteristics and also showed that they were benign overgrowths of an arteriovenous anastomosis which are present normally in the stratum reticulare of the cutis. Recent reviews of this subject and reports of cases have been made by Bailey,¹ Freudenthal,⁴ Stout,¹² and Lewis and Geschickter.⁷ Radasch¹¹ in a recent review of the literature was able to find reports of ninety cases, four of which were instances of multiple tumors.

Normal Histology and Physiology

It was Masson who first proved that the glomus exists normally in the subcutaneous tissue and that glomal tumors result from hypertrophy. Sucquet¹³ first described arterio-venous shunts which he found by making special injections into arteries of material which he noticed went directly into the veins without entering any capillaries. Later Hoyer⁵ described and demonstrated similar anastomoses in animals. Popoff¹⁰ has recently made an extensive study of these vascular anastomoses both in normal and pathological conditions. He found that they were more numerous in the nail beds, tips of fingers, palms and soles than any other part of the body.

A glomus consists of various parts, first the afferent arteriole, which is a small branch of the subcutaneous artery. This arteriole gives off sev-

†Dr. Becker is with the Duluth Clinic, Duluth, Minnesota.

eral smaller branches which supply nutrition to the reticular and supporting tissue of the glomus. The arteriole then leads directly into the anastomotic vessel (Sucquet-Hoyer canal), which now becomes considerably modified (Figs. 1 and

consisting of delicate collagenous fibres and peripheral to this is a denser lamellated collagenous tissue which forms an irregular capsule around the glomus and it is in the meshes of this tissue that the collecting veins are found.

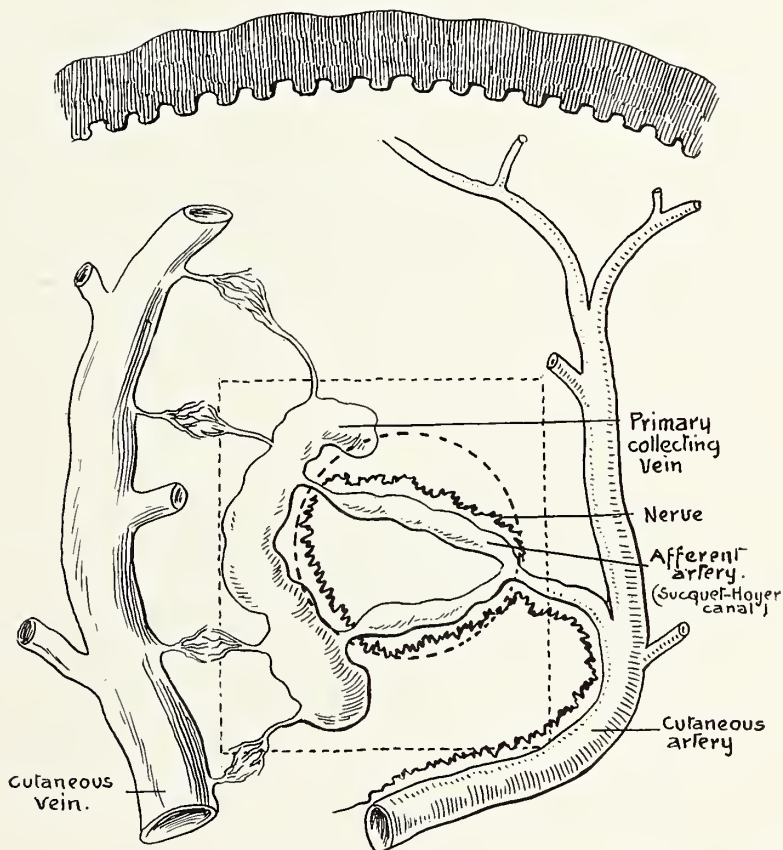

Fig. 1. Schema of normal glomus. The portion in the dotted square is the glomus proper and the portion in the dotted circle is enlarged in Figure 2. Reproduced by courtesy of Doctors Fred Weidman and Fred Wise.

2). Its course is very tortuous or "S"-shaped; the endothelial cells are cuboidal, increased in size, and two or three rows thick. The internal elastic lamina is lost and the muscular coat consists of an indistinct inner longitudinal and outer circular layer. Amid the muscle cells are large clear epitheloid cells or so-called glomus cells. The outer zone consists of a loose collagenous reticulum, in the meshes of which are found numerous non-medullated nerves. Around the canals like a plexus are the collecting veins into which they empty; these veins are thin walled and poor in muscular tissue. They in turn empty into subcapillary venous plexus and thence into the deeper veins. Around the vessels is an area

Popoff found the glomus entirely lacking at birth but that it begins to develop rapidly post-natally, undergoing atrophy around sixty years of age. The anastomoses act both locally and generally in the regulation of heat. If a local area is cold, the glomus diverts blood from the capillaries to its collecting veins, which have a large surface area. Generally they may aid in conserving or lowering the body heat as above. When the body temperature is elevated the glomus rushes blood to the surface veins for cooling and when the body temperature is low it diverts the blood from the surface to conserve its heat. The glomus also aids in regulating the flow of blood through an extremity by either allow-

ing it to fill the capillary bed or by diverting it into the collecting veins, where it is rapidly placed back in the general circulation. Since the glomus is absent in the premature baby, it is rather convincing evidence that it is probably a great factor

give origin to the smooth muscle elements of the glomus; others think they are angioblasts giving rise to blood vessels of the growth. Stout was able to demonstrate, in his histologic sections, areas around blood vessels where the glomus

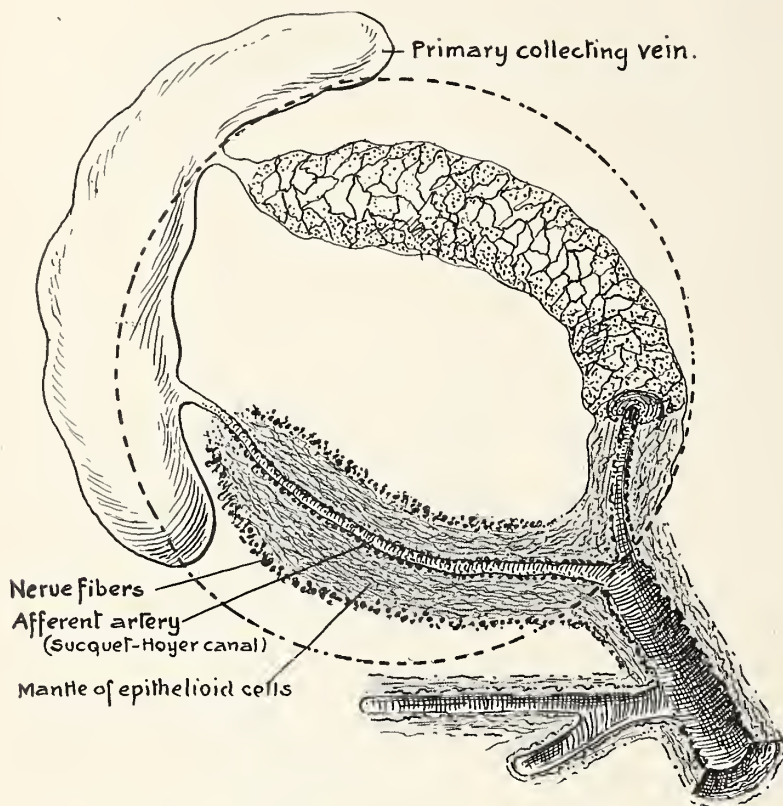

Fig. 2. Enlarged portion of the glomus illustrated in Figure 1.

in controlling local and body heat. Masson believed that the glomus aided in tactile sense by its ability to regulate vascular pressures and thereby interstitial pressures. He believed that was the reason why they were so plentiful in the areas in which the tactile sense was best developed, namely the finger tips. Popoff also found that the normal glomus was increased in number in arteriosclerosis and in extremities in which gangrene associated with diabetes was developing.

The glomal tumor represents a benign hyperplasia of all of the elements contained in the normal glomus, especially the so-called epithelioid cells. These cells are peculiar and closely resemble the cells of the glomus coccygeum.¹² They are undoubtedly mesoblastic in origin. Some authors believe they are myoblasts and

cells were transforming into smooth muscle cells.

Mason and Weil⁸ found that the distribution of the tumors as to sex was about equal and that they occurred from eight to eighty-two years of age. In reviewing thirty-four cases they found twenty-one were on the upper extremities and two-thirds of these were subungual. The lesions are also more frequent among Jews, who are more prone to develop disturbances of the sympathetic innervation of the extremities.

Report of Cases

Case 1.—Mrs. L. T., a forty-five-year-old white woman of Scandinavian descent, consulted the University Hospital Staff because of recurrent attacks of upper right quadrant pain which was interpreted by the Surgical Department as cholelithiasis. She was seen in consultation by the Dermatology Staff because of a

painful tumor on the right forearm that had been present for ten years or more. With the slightest touch or exposure to cold air she would feel paroxysms of severe pain which would shoot up and down her arm.

these patients on the slightest pressure, or even changes in temperature, special studies were performed to demonstrate nerve fibers. At the suggestion of Dr. A. T. Rasmussen one half of the tissue which was removed from the first patient was fixed in absolute alcohol, to

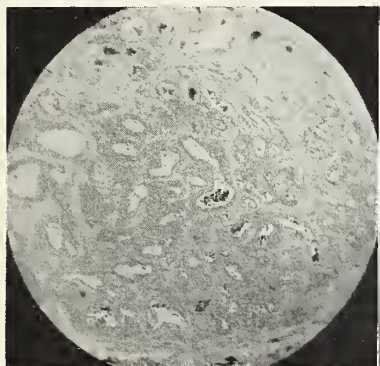

Fig. 3. Section of glomus tumor under low power magnification showing numerous vascular spaces which are surrounded by a mantle of epithelioid-like cells.

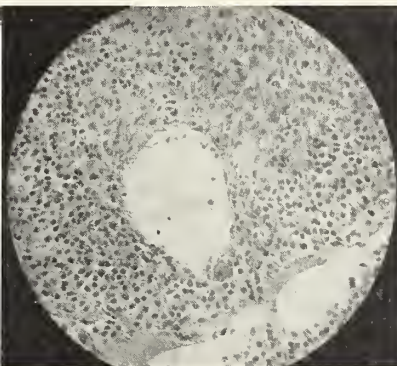

Figure 4. High power magnification of one of the vascular spaces as shown in Figure 3. The lining endothelium may be seen and the epithelioid (glomus) cells in detail.

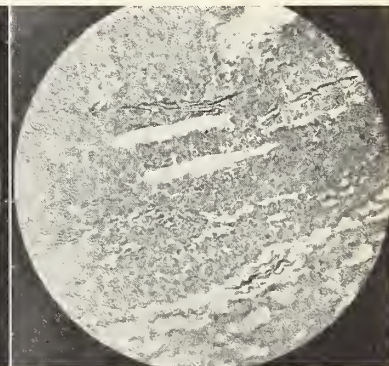

Fig. 5. High power magnification of area similar to Figure 4, showing nerve fibers among glomus cells and in supporting tissue.

Examination of her skin revealed a semi-solid bluish red tumor about the size of the head of a lead pencil located on the dorsal surface of the right forearm. With the slightest pressure on the lesion, the patient experienced excruciating pain. The lesion was completely excised under local anesthesia. The tumor was divided in half, one portion being fixed in 70 per cent alcohol, then blocked in paraffin, sectioned and stained with hematoxylin and eosin.

Microscopic examination under low power objective showed the tumor to be encapsulated by connective tissue. The central portion consisted of numerous vascular spaces, lined by large cuboidal endothelial cells (Figs. 3 and 4). Next to these were large polyhedral cells with an acidophilic cytoplasm and a dark staining nucleus. These cells varied in thickness from three to four around some blood channels to ten or twelve around others, and are those described as epithelioid or glomus cells. Interspersed between and among the cells were collagenous fibers as a supportive structure. The diagnosis of the histologic section was that of a "glomus tumor."

Case 2.—Mr. A. M., fifty-eight years of age, consulted Dr. L. A. Whitesell because of a small painful growth on the medial aspect of the left knee. The growth was so painful that he devised a protective bunion pad to remove garment pressure.

Examination of his skin showed a small slightly elevated bluish red nodule measuring two by three centimeters, located over the medial aspect of the head of the left tibia. The tumor mass was completely excised under local novocaine infiltration anesthesia. Histologic examination of the tumor tissue was similar to that described in Case 1 and the diagnosis was "glomus tumor."

Because of the excruciating pain that is elicited by

which six drops of ammonium hydrate per 100 c.c. were added. The tissue was stained by Cajal pyridine silver stain of Dr. Larsell⁶ and then imbedded in paraffin and sectioned. Microscopic examination of this tissue after staining by this special technic showed numerous nerve fibers entering through the capsule and spreading out into the reticular tissue, where they seemed to terminate about the glomus cell (Fig. 5).

Comment

The two cases reported are typical of an unusual neurovascular tumor which has created intense interest in the literature of recent years. These lesions are clinically very important, primarily because of the excruciating pain which they produce. The frequent occurrence of these growths below the finger nails makes the diagnosis less obvious, but careful examination will usually show discoloration of the nail in a small area and occasionally erosion of the terminal phalanx may be seen on roentgen examination. A rich supply of nerve fibers terminates about the epithelioid-like cells that are present around the vascular spaces. It would seem apparent then that changes in tension within the vascular spaces would account for the severe pain that occurs in these tumors. The lesions are cured by simple surgical excision and do not respond to any type of radiation therapy. Histologic examination will readily confirm the diagnosis. In approximately a hundred cases now reported in the

literature, no evidence of malignancy has been found.

Summary

Two typical cases of glomus tumors have been described. The histology and physiology of these benign growths have been discussed, especially the rich supply of nerve fibers which apparently innervates the vascular spaces. These nerves probably account for the characteristic pain present on the slightest manipulation. Surgical excision is usually curative.

PERIODIC HYPERMOMNIA, HYPERPYREXIA, AND HUNGER, SECONDARY TO EPIDEMIC ENCEPHALITIS*

E. M. HAMMES, M.D.

Saint Paul, Minnesota

FULTON⁸ in his recent textbook, "Physiology of the Nervous System," states that five distinct syndromes of the hypothalamus can be recognized. In some instances these syndromes may occur fairly well isolated; in others evidence of the entire group may manifest itself, depending on the location and extent of the lesion and the rapidity of its development. These syndromes may be designated as (1) hyperthermia, (2) diabetes insipidus and emaciation, (3) the adiposogenital syndrome, (4) hypersomnia with disturbed thermal regulation, and (5) autonomic epilepsy.

In association with these syndromes, personality changes and other psychic manifestations may present themselves, varying from simple depression to any of the major psychoses. Periods of excitement tend to develop from lesions of the anterior hypothalamus, while depressed¹³ lethargic, and even catatonic states may be produced by posterior lesions.

Many cases of hyperthermia and hypothermia associated with lesions in the hypothalamus are recorded in the literature. The combination of hypersomnia with hyperthermia occurring at irregular but quite frequent intervals over a period of over four years, with periods of hunger,

is of sufficient interest to warrant this report. Although no pathologic studies are available at the present time, the clinical manifestations are quite typical of a hypothalamic syndrome.

Report of Case

Attack of epidemic encephalitis: aphasia for two years; recurrent attacks of hypersomnia and hyperthermia developing soon after encephalitis; periods of persistent hunger.

The patient, a boy four years and nine months of age, was referred to us by Dr. E. J. Fogelberg on December 8, 1937. (Now aged five years, six months.)

Family history was negative except that the father had migraine for many years.

The patient was a cesarean section delivery at eight and a half months. He developed normally, walked at ten months, and was able to talk some at the time of the onset of the encephalitis at the age of sixteen months. During his first year he had chicken-pox and measles without any complications. He is right-handed. At sixteen months of age, in July, 1934, he developed encephalitis, with two generalized convulsions during the first twenty-four hours. His temperature varied between 100 and 105 degrees F. Following the convulsions he apparently slept for about twenty hours. He gradually recovered but remained aphasic until the winter of 1936, when he began to say a few words. His vocabulary gradually increased and his speech is quite normal at present. During the entire period his vesical functions were normal. He expressed his wants by pointing to what he desired.

About one month after he recovered from his en-

*Read at the meeting of the Central Neuropsychiatric Association, Minneapolis-Saint Paul, Minnesota, October 8, 1938.

cephalitis, in August, 1934, he would have attacks of gradually becoming sleepy, and after a short period would fall into what appeared a deep normal sleep. He would sleep from twenty-four to seventy-two hours, then awaken, would dress himself, appear normal, and go out and play with other children. During these attacks of hypersomnia he could be aroused, would take a little food and again fall asleep while eating. There have been no involuntaries. On several occasions he would awaken, urinate, and be asleep before he had completely emptied his bladder. During the attack he lies quietly and relaxed, except on five occasions, when his right arm was restless and he would move it about, but there were no convulsive jerkings. He has slept continuously for forty-eight hours without taking food or drink, or urinating.

He may have prodromal symptoms, such as an occasional occipital headache or a feeling of drowsiness for about fifteen minutes before falling asleep. He realizes that an attack is coming on and does his utmost to keep awake. Before an attack he frequently tells his mother, "I am so sleepy I cannot stay awake," and then begs her repeatedly to remain with him if he should fall asleep. He sits down, is very quiet, and within a few minutes is sound asleep. These attacks occur at irregular intervals, averaging about two a month. He has fallen asleep on the railroad track, on the highway, in the field, on the playground, and at home. The mother estimates that he has had over one hundred of these during the past four years. His last attack occurred on August 21, 1938, was of fifty hours' duration, and was accompanied by a hyperthermia of 104 degrees F.

His temperature, which has been noted daily for over three years, has been normal except during the periods of hypersomnia. About one-half hour before the hypersomnia manifested itself he would develop a temperature of about 100 degrees F. From three to four hours after he has fallen asleep the temperature would reach its maximum, 103 to 105 degrees. It would continue at this level until he began to awaken and then rapidly return to normal. Cold water enemas and cold baths would reduce the temperature about two degrees, without any appreciable effect on the hypersomnia. His pulse averaged about 130 and respirations 26 per minute during the attack. They were not accompanied by sweating or any evidence of vasomotor reactions. The attacks of hypersomnia and hyperthermia always accompanied each other and have never occurred separately. They have continued since the onset without any special variation in their frequency or severity.

During the past year, since September, 1937, he has had periods of about twelve hours' duration during which time he would continuously beg for food. The mother stated that he has had about twenty of these attacks. She describes them as "mental hunger." He would eat a good meal and within a few minutes insist that he was so hungry and wanted food. When the food was given to him, he refused to eat because he said that he felt so "full." Within a short interval

he would repeat the same request. This would continue during the entire day until he finally fell asleep. Upon awakening the following morning his food hunger had disappeared. The last one occurred seven days ago. During these periods his food and fluid intake were normal. These attacks bore no relation to the hypersomnia and hyperthermia, and never occurred during or immediately before or after the hypersomnia.

His urinary output has been normal. There has been no evidence of polyuria or polydipsia. He has not manifested any personality changes or temper tantrums. He plays normally with his toys and with other children and is anxious to begin school. He has an occasional period when his memory seems slightly impaired, but the greater part of the time he is alert and remembers well. His nocturnal sleep is normal. He has had no petit mal attacks or convulsive seizures since the encephalitis.

Physical examination reveals a well nourished, well developed male, weighing 48 pounds. Complete examination, including the sexual organs, showed no abnormality.

The neurological examination was also negative throughout. Pupils, fundi, eye movements, other cranial nerves, reflexes, sensation, and so forth, were negative. Mentally he was alert, answered questions fairly well and executed the various tests promptly and correctly. His memory was normal.

His temperature was 98.6 degrees F., pulse 84, taken at 3 p. m. yesterday; hemoglobin 82 per cent; red blood cells 4,700,000; leukocytes 8,400; differential count normal; blood pressure, systolic 96, diastolic 45; blood Wassermann negative. The spinal fluid on December 9, 1937, was clear and colorless, under pressure of 220 mm. of water. It contained one cell, a trace of globulin, and the Wassermann negative and the colloidal gold curve normal. The quantitative sugar and quantitative protein were within normal limits. Roentgenological studies of the skull, sella tursica, and chest were normal. No encephalograms were made. Basal metabolic rate was +2 per cent.

The sugar tolerance test gave the following values for blood sugar: after fasting, 70 mg. per 100 c.c.; one-half hour after ingestion of 100 gm. of dextrose, 98 mg; one hour, 78 mg, and two hours, 69 mg. The water balance was normal.

He had had a tonsillectomy at the age of thirty months and has been given benzedrine, without any noticeable effect on his attacks.

Masten¹² observed a somewhat similar case.

In December, 1935, a girl of seven had an attack of illness, manifested by sleepiness, headache, earache, sore throat, and abdominal pain. Within one week she complained of weakness of both legs and soon after could not stand. The acute illness continued for ten days with fever of 104.4 degrees rectally. The legs remained weak until July, 1936, when strength returned suddenly. In September, 1936, she had a period of deep sleep of twelve hours' duration, and similar at-

tacks in the fall and winter of 1937. Upon awakening she screamed and held her head. Occasionally she sobbed continuously for two or three days, her only reason given for crying being that she was tired. During these days she was very irritable. The day following her attacks of hypersomnia she ran a high temperature. She had also been manifesting some personality changes. Formerly she was an active, keen youngster. Since her illness she had become quiet, taking no part or interest in the activities of her brothers and sisters and preferring to sit and rock with a doll in her lap.

Comment

Our case is of interest because of the isolated syndromes of recurrent attacks of hypersomnia and hyperthermia, extending over a period of four years. Lethargic encephalitis frequently produces lesions in the hypothalamus. Eaves and Croll⁶ have found this region invariably involved in encephalitis, and more extensively than any other portion of the brain except the substantia nigra. Disturbances in the sleep rhythm and the presence of a sleep center in this region were described by von Economo⁵ in 1930. Later clinical and experimental evidence indicate that the posterior group of the hypothalamic nuclei, including the mamillary body and the nucleus hypothalamicus posterior, are involved. According to Hess, stimulation of this region with a faradic current induces hypersomnia. Ranson,¹⁵ however, has never been able to produce sleep by faradic stimulation of the hypothalamus, but all the reactions were those that accompany emotional excitement. Fulton and Bailey⁹ also reported cases of expanding tumors in this region associated with pathologic sleep. Bailey⁹ has further observed that manipulation of the posterior hypothalamus and central gray of the Sylvian aqueduct causes loss of consciousness, which is not so prone to occur if the anterior hypothalamus is irritated.

The importance of the hypothalamus for the regulation of body temperature has been reviewed repeatedly in the literature. Frazier, Alpers, and Levy⁷ have conclusively demonstrated that mesially placed bilateral lesions in the floor of the third ventricle in cats produce complete loss of temperature control, resulting in a sustained hypothermia. The lesion involved the floor of the third ventricle corresponding to the nucleus hypothalamicus anterior in cats and the substantia grisea in man. In no instances were

they able to produce hyperthermia by lesions placed in the hypothalamus. Alpers,¹ however, reported two cases of tumor in the pituitary area in which death was accompanied by severe hyperthermia. The lesions were found in the floor of the third ventricle, more particularly in the substantia grisea. Jacoby and Rohmer observed that severe and prolonged hyperthermia could be produced by the introduction of mercury into the ventricular system, especially into the infundibular region. Cushing in his Lister Memorial lecture stated that complete emptying of the ventricles of the brain in children has been followed by hyperthermia. Ranson and his coworkers¹⁴ in their experiments on monkeys have demonstrated that postoperative hyperthermia develops when bilateral lesions are made in the lateral part of the rostral portion of the hypothalamus. Hypothermia develops when the bilateral lesions are situated dorsolateral to the rostral part of the mammillary bodies. The hyperthermia is usually transient and of about twenty-four hours' duration, while the hypothermia may continue for days, even as long as a month.

Davidson and Selby⁴ reported a case of adiposogenital dystrophy with hypersomnia and hypothermia. During a period of over three months, the average temperature was about 92.5 degrees F. Postmortem studies revealed an angioma situated in the floor of the third ventricle. The prolonged hypothermia was evidently due to an extensive involvement of the tuber nuclei and the mammillary bodies. Davidson and Friedman³ reported the case of a twenty-nine-day old infant who during its life time manifested constant fluctuations of hypo- and hyperthermia which tended to approximate the environmental temperature. Pathologic studies revealed that most of the hypothalamic nuclei, especially the mesial group, were destroyed by an infiltrating neuroblastoma. Fulton⁸ states that in man usually both mechanisms of heat loss and heat production are disturbed because most lesions tend to involve both groups of nuclei simultaneously, due to the antero-posterior narrowing of the hypothalamic area in man.

The complaint of periods of continued hunger presents another interesting phase in our case. Beattie² and others have shown that stimulation of the mid-line nuclei in the region of the tuber evoke increased peristalsis of the stomach and

intestines, along with other phenomena, indicating a sympathetic outflow.

Levin,¹¹ under the title of "Periodic Somnolence and Morbid Hunger," reviewed ten cases from the literature, including one of his own. No pathologic findings were recorded. His hypothesis is that "periodic somnolence hunger" is due to excessive "inhibitability" or exhaustibility of the highest cerebral centers, particularly the highest motor centers. He bases this opinion on the results Fulton¹⁰ and his coworkers obtained after bilateral removal of parts of the frontal lobes in monkeys. The excision of these areas produced increased appetite, gastro-intestinal motility, and frequently intussusception. Hyperpyrexia, however, was not an accompaniment.

CARCINOMA OF THE CERVIX UTERI: FACTORS INFLUENCING PROGNOSIS*

HARRY H. BOWING, M.D.

Rochester, Minnesota

IT IS generally agreed that the following factors are important in determining the prognosis in the average case of carcinoma of the uterine cervix: (1) extent of the local lesion; (2) age of the patient; (3) general health and vigor, and (4) resistance to the malignant growth. A statistical study of 1,491 cases of carcinoma of the cervix encountered in the Section on Therapeutic Radiology of The Mayo Clinic from 1915 to 1929, inclusive, furnishes some additional data. On the basis of these data, the following topics as well as the four prognostic factors already mentioned will be considered: (1) influence of sterility and fertility; (2) influence of biopsy; (3) histologic types; (4) grade of malignant change; (5) technic of treatment employed; (6) experience of the radium therapist; (7) hospital mortality, and (8) treatment of recurrent lesions.

Statistical data and clinical impressions have

definite limitations in the consideration of these topics; however, these data and clinical impressions may indicate in a measure a valuable trend or may constitute a definite lead and may indirectly assist in an attempt to formulate a worthwhile opinion. Some of the topics do not lend themselves at all to a statistical analysis. It is impossible to arrange these topics according to their importance as there are many factors which influence the choice or selection.

Extent of the Local Lesion

The extent or stage of the primary lesion and the extent or stage of the secondary lesions always have been and are today of major importance to the physician in deciding whether or not the patient has a chance for cure or palliation. A suitable classification is essential for proper interpretation of the immediate and late results. The extent of the primary and secondary lesions is the basis of the following classification: Stage 1 denotes that the primary lesion is limited to the cervix of the uterus. Stage 2 indicates that the

CARCINOMA OF THE CERVIX UTERI—BOWING

TABLE I. CLASSIFICATION OF CARCINOMA OF THE UTERINE CERVIX ACCORDING TO STAGE OF INVOLVEMENT IN 1,079 CASES*

Stage of involvement	Cases	Per cent
1	13	1.2
2	85	7.9
3	825	76.4
4	156	14.5
Total	1,079	100

*In 412 of the series of 1,491 cases the lesions had been modified by previous treatment.

TABLE II. RESULTS OF TREATMENT OF CARCINOMA OF THE UTERINE CERVIX BY IRRADIATION ALONE ACCORDING TO STAGE OF INVOLVEMENT

Stage of involvement	Patients treated	Patients traced	Lived five or more years after treatment	
			Patients	Per cent of those traced
1	13	13	9	69.2
2	85	78	47	60.2
3	825	753	224	29.7
4	156	138	9	6.5
Total	1,079*	982 (91.8%)	289	29.4

*Fourteen, or 1.3 per cent, of the 1,079 patients died in the hospital during the course of treatment.

primary lesion involves the cervix and has caused moderate infiltration of the vaginal wall or the parametrial tissues; in this stage the uterus is movable. Stage 3 indicates that the primary lesion has extended well beyond the cervix infiltrating the parametrium and has caused definite fixation of the uterus. Stage 4 indicates that the primary and secondary lesions have caused extensive local infiltration and involvement of pelvic structures and that there is wide fixation of the uterus with or without metastasis to distant regions.

Table I shows the stage of involvement in 1,079 cases in which the lesion had not been modified by previous treatment. The data in this table were obtained from the clinical, surgical and special records. In more than 90 per cent of the 1,079 cases, the disease was beyond any type of curative surgical intervention.

Table II shows the stage of the disease and

TABLE III. RESULTS OF TREATMENT OF CARCINOMA OF THE UTERINE CERVIX BY IRRADIATION ALONE, ACCORDING TO AGE OF THE PATIENTS

Age, years	Patients treated	Patients traced	Lived five or more years after treatment

Total	1,490*	1,351* (90.7%)	362	26.7

*One patient, who was between eighty and ninety years of age and who lived five years after the completion of treatment, is not included in this table.

the number of patients who lived five or more years after the completion of irradiation. Although the number of cases in which the disease was classified as stage 1 or 2 is comparatively small, the data in this table seem to indicate that the stage of involvement does have a definite relationship to the prognosis.

Age of the Patient

In general, young adults or elderly persons who have carcinoma are adjudged to respond poorly to treatment and the ultimate prognosis is not good. The presence of degenerative disease frequently influences adversely the prognosis for elderly persons.

Table III shows the relation of the age of the patient to the prognosis in 1,490 of the 1,491 cases. This table does not include one patient who was between eighty and ninety years of age and who lived five years after the completion of treatment. The total number of cases were divided into three groups according to the age of the patients. The data in this table indicate that the age of the patient does not have any appreciable influence on the prognosis. Evidently, patients who receive individual radium therapy for carcinoma of the uterine cervix, regardless of age, have about an equal chance for survival for five years or more. The older age group have a slight advantage in this regard over the younger age groups.

General Health of the Patient

From the standpoint of the radiotherapist, the general health and vigor of the patient are very important. Such complications as second-

any infection and secondary anemia tend to decrease the resistance of the patient and retard the response of the patient to treatment. Patients who are vigorous and in good general health can tolerate adequate doses of radium and roentgen rays very well. In cases of advanced or extensive carcinoma in which complications have affected the general health of the patient, both local and general supportive measures are necessary and only limited radiotherapy can be employed.

The statistical data concerning the general health of the 1,491 patients are incomplete. From clinical experience we may conclude that the general health of the patients who have stage 1 and 2 lesions is good. Patients who have stage 3 lesions may show a moderate secondary anemia or patients with recent severe hemorrhage may need special consideration before treatment is started; as a rule patients who have stage 4 lesions experience comparatively a severe break in general health.

The most important consideration is the healing or absorption of the malignant lesion or lesions; in other words, the bodily reactions should be at their best in order that the malignant lesion may lose its malignant features and the affected part if possible may be restored. Usually, cervical carcinoma is secondarily infected. These two pathologic conditions, carcinoma and infection, make a simultaneous demand on the patient's health. With proper treatment and in a relatively brief period, the malignant lesion and the inflammation will respond. The local cellulitis with minimal ulceration does not require any special treatment. Pelvic cellulitis with fever has responded well to chemotherapy, sulfanilamide for example. Pelvic abscess may require surgical treatment. Infection by way of the blood stream is usually a serious complication. Co-existing pyometritis will subside after simple procedures, such as uterine drainage.

Resistance to the Malignant Growth

As yet we have no clinical or laboratory test that would definitely indicate resistance or non-resistance to the malignant growth. Clinically, there are two varieties of cervical carcinoma, the medullary type and the infiltrating or ulcerating type. Theoretically, the medullary type begins as a superficial growth in the epithelium of the portio vaginalis and proceeds to enlarge into the

vaginal cavity. Its infiltrating characteristic is a relatively minor feature. The ulcerating type probably begins within or beneath the epithelium of the lower uterine segment as a nodular growth. It infiltrates the uterus and parametrial tissues readily, and as growth proceeds it tends toward ulceration. Clinically, the medullary variety seems to grow more rapidly than the ulcerative variety. There is a possibility that the patient's resistance or lack of resistance may be reflected in the gross characteristics of these two comparatively distinct types of carcinoma. Little is known about the time element or speed of development of any malignant lesion of the uterine cervix. As a rule, the history, regardless of how carefully it is taken, cannot be relied on for determining the actual time of onset of the disease. The correlation of accumulated data seems tedious and the many variations make the problem difficult of solution. However, careful clinical studies will add to our knowledge and eventually we may be able to understand better these characteristics that we are considering. Results of radiation therapy have definitely proved that with proper treatment the patient has the power or ability to heal or restore the affected part to normal. Evidently this phase of our problem was not fully appreciated by early workers in the field of malignant disease. Naturally, therefore, everything possible should be done to support the patient in conjunction with adequate irradiation and thus assure satisfactory recovery.

The Influence of Sterility and Fertility

The etiology of carcinoma of the uterine cervix is unknown, in that there are no benign lesions of the cervix that have been proved to be always premalignant. Among the predisposing factors of cervical carcinoma, lacerations, erosions, eversion and the like are always considered of importance. Because pregnancy is the most common single cause for cervical trauma, a record of the sterility and fertility of the total group was compiled.

The civil state of the total 1,491 cases is as follows: There were 1,473 (98.8 per cent) married patients and eighteen (1.2 per cent) single patients. One or more pregnancies occurred in each of 1,320 patients, an incidence of 88.5 per cent. According to the records of 149 patients (10 per cent), pregnancy did not occur. In

twenty-two records (1.5 per cent), the incidence of gravidity was not stated. There were 4,792 pregnancies that proceeded to full term and 973 miscarriages were recorded for the entire group. Excluding the aforementioned twenty-two histories, the average number of pregnancies for the group was 3.3 pregnancies per patient.

TABLE IV. RESULTS OF TREATMENT OF CARCINOMA OF THE UTERINE CERVIX BY IRRADIATION ALONE. PERCENTAGE SURVIVAL RATES ACCORDING TO THE STERILITY OR FERTILITY RECORDED

	Patients treated	Patients traced	Lived five or more years after treatment	
			Patients	Per cent of those traced
One pregnancy	262	242	67	27.7
Two or more pregnancies*	991	896	250	27.9
No pregnancy	149	136	28	20.6
Miscarriage (only)	67	60	17	28.3
Not stated	22	18	1	5.6
Total	1,491	1,352	363	26.8

*From 2 to 15 pregnancies.

The percentage survival rates are listed in Table IV according to the data on sterility or fertility in the clinical record. Each of 991 patients experienced two or more pregnancies that proceeded to full term and 250 patients (27.7 per cent) lived five or more years after treatment. There were 262 patients who experienced one full-term pregnancy and sixty-seven of these (27.7 per cent) lived five years or more after treatment. There were 149 patients who did not experience pregnancy and of these twenty-eight (20.6 per cent) lived five or more years after treatment. Sixty-seven patients experienced miscarriage, only, and of these, seventeen patients (28.3 per cent) lived five or more years after treatment.

Evidently carcinoma of the uterine cervix is a disease of married women; however, it is infrequent among Jewish women.^{1, 4} Furthermore, the number of pregnancies did not significantly influence the prognosis or the survival rate for five years and more among those groups studied, and the lowest percentage of five-year survivals or more occurred in the group in which no pregnancies occurred.

The Influence of Biopsy

For our purpose, there are two kinds of biopsies. One may be designated a surgical biopsy and may be considered as a minor surgical procedure, whereas the other may be designated a therapeutic biopsy. The surgical biopsy usually requires administration of a general anesthetic agent which permits a more liberal bimanual palpation of the pelvic structures, especially if the patient is nervous or apprehensive. Thus, it furnishes valuable, additional information. The speculum and tenaculum are placed to afford exposure and if the lesion is only partly movable, the maintenance of adequate exposure may be very tedious. The pathologic tissue is removed by incision, which may extend into the normal tissue. As a rule, the specimen consists of a piece of tissue representative of the part and therefore most reliable for histologic study. The actual cautery may be applied to control bleeding or one or more sutures may be necessary. A gauze pack is placed in the vagina.

The therapeutic biopsy is performed at the time of the first application of radium. A general anesthetic is not necessary. The patient is placed in the knee-chest position. A speculum and some type of direct light allow for ample exposure. The entire vaginal portion of the pathologic lesion can be readily inspected and a representative site can be selected from which to remove the specimen. Trauma is reduced to a minimum in that a tenaculum is not used. A bit of tissue, the size of a grain of wheat, is removed with a tracheal biopsy instrument in the average case. The area selected is free of necrosis and may be considered as an everted surface of the malignant infiltrating lesion. The normal tissues are not disturbed. There is very little bleeding, if any. The number of positive findings on the small piece of removed tissue is very high; only occasionally may the pathologist ask for another specimen.

An ideal procedure for biopsy would be one without trauma or risk to the patient. The first procedure mentioned is definitely traumatic and there is some attendant risk, whereas the latter procedure in a measure does approach the ideal and carries very little risk, if any. Biopsy is an essential part or feature of the diagnostic procedures and should be a routine requirement in all cases selected for treatment. In selected

cases, the surgical biopsy together with dilatation and curettage, may be necessary to establish the diagnosis. Especially is this true, should the history and gross appearance of the cervical lesion be atypical; therefore everything possible should be done to establish the diagnosis of carcinoma of the uterine cervix. A failure to diagnose stage 1 or 2 lesions is a serious matter for, in the interval, the patient may pass into the third or fourth stage of the disease in which the ultimate prognosis is only fair or palliation is all that can be expected.

I am certain that the risk of a surgical biopsy and especially the very slight risk of a therapeutic biopsy is outweighed by the positive information it affords.

The Histologic Types

More than 90 per cent of malignant lesions of the uterine cervix are squamous-cell epithelioma. About 5 to 8 per cent are adenocarcinoma and the remainder are a combination of squamous-cell epithelioma and adenocarcinoma.²

The gross appearance of the lesion does not allow determination of the histologic type. Infiltrating lesions probably predominate. The medullary lesion of the portio vaginalis is usually squamous-cell epithelioma, grade 3 or 4, and is prone to necrosis, hemorrhage and secondary infection, whereas infiltrating squamous-cell epithelioma or adenocarcinoma occurring in the portio supravaginalis tends toward early infiltration and may block the cervical canal, obstructing the flow of uterine secretion and ultimately bringing about various degrees of pyometritis and pain that simulate menstrual pelvic distress. The latter complication occurs as a feature of the character and the site of the malignant lesion rather than as a result of radium therapy. Adenocarcinomas are in the minority and the small number for which treatment has been given were of the lower grades of malignancy and as a rule they furnished a slightly better prognosis than squamous-cell epitheliomas with irradiation therapy.

Grade of Malignant Change

The grade of malignant change is a very valuable contribution to our knowledge of malignant disease. A broad view of malignant disease taught us that the individual, the site of involve-

TABLE V. RESULTS OF RADIATION THERAPY FOR CARCINOMA OF THE UTERINE CERVIX, BASED ON THE GRADE OF MALIGNANT CHANGE

Group	Patients treated	Patients traced	Lived five years or more after treatment	
			Number	Per cent*
Grade 1	5	5	2	40.0
Grade 2	135	122	40	32.8
Grade 3	407	362	125	34.5
Grade 4	336	307	105	34.2
Total	883	796†	272	34.2

*Percentage of traced cases.

†90.7 per cent traced, total 1,491 cases.

ment and the gross characteristics of the disease did furnish valuable data; however, their interpretation was not very clear. From the standpoint of the surgeon and the radium therapist we can assume that grading of the malignant change does furnish an opinion of the pathologist to guide our therapeutic endeavors. The surgeon fully appreciates the fact that the majority of patients who have malignant disease of high grade do poorly regardless of the method of surgical intervention, whereas carcinomas of low grade have a much better surgical prognosis. For the radium therapist, grading of neoplasms has furnished the basis for a therapeutic rationale.

Briefly stated, there are two elements in a malignant tumor. One is the characteristic tissue cell that makes up the parenchyma of the tumor and the other is the stroma or supporting matrix with its varying degrees in amount and kind of cellular infiltration. It is reasonable to assume that there are intrinsic and extrinsic factors that influence these elements. These reactions are very complex and for the present may be considered a life process that in a measure can be influenced by the factors employed in therapeutic radiology. Surely, this is a phase of radiosensitivity the nature of which is not too well or only very incompletely understood. The more we master or control these influences or reactions, the greater or better will be the result of our therapeutic endeavors. As has been stated, carcinomas of high grade respond poorly to surgical intervention and respond more satisfactorily to radiotherapeutic methods, as is clearly shown in the statistic results obtained in cases of carcinoma of the uterine cervix. Our surgical experience further shows that low grade car-

CARCINOMA OF THE CERVIX UTERI—BOWING

TABLE VI. AGE ACCORDING TO GRADE OF MALIGNANT CHANGE*

Age, years	Grade 1		Grade 2		Grade 3		Grade 4	
	Number of patients	Per cent	Number of patients	Per cent	Number of patients	Per cent	Number of patients	Per cent
20-29	0		0		9	56.3	7	43.7
30-39	0		24	14.2	71	42.0	74	43.8
40-49	3	1.0	40	13.7	120	41.1	129	44.2

Total	5	0.6	135	15.3	336	38.0	407	46.1

*883 cases.

cinomas respond well to surgical intervention. With these data as a working basis, some investigators have assumed that carcinomas of low grade are radioresistant. Evidently the latter conclusion is only partly correct in that such carcinomas will respond to proper treatment and that adequate treatment seems to give at least the same degree of good results for carcinomas of both low and high grades. It is incorrect to assume that, because carcinomas of high grade are radiosensitive, carcinomas of low grade should not be radiosensitive.

The data in Table V are submitted to corroborate the aforementioned statement regarding influence of grade of malignant change on the five-year survival rate. There were 883 cases in which the lesions were graded and 796 of these cases were traced. Of these 796 patients, 272 lived for five years or more, a survival rate of 34.2 per cent. The total cases are subdivided according to the grade of pathologic change. Treatment for lesions graded 3 and 4 gave equal percentages of five-year survival rates which are similar to the average percentage for the group. There are very few lesions grade 1, and when encountered they prove to be adenocarcinoma. The grade 2 lesions are also in the minority. The five-year survival rate in cases of grade 1 lesions was 40 per cent; grade 2 lesions, 32.8 per cent. In general, tumors of low grade in our experience have given a slightly increased survival rate when compared with lesions of high grade, provided that the patients are not treated according to rule but according to their mode of response to the treatment.

TABLE VII. THE AGE GROUPS OF ALL CASES COMPARED TO THE AGE GROUPS OF THE GRADED CASES.

Age, years	All cases		Graded cases	
	Total	Per cent	Total	Per cent
20-29	28	1.9	16	1.8
30-39	284	19.0	169	19.1
40-49	496	33.3	292	33.1
50-59	452	30.3	267	30.2
60-69	208	13.9	125	14.2
70-79	22	1.5	13	1.5
80-89	1	0.1	1	0.1
Total	1,491*		883†	

*58.9 per cent of all cases.

†91.9 per cent of patients traced.

Influence of Age on Grade of Malignant Change

The influence of age on grade is also misunderstood in that some observers are of the opinion that young patients have carcinomas of high grade and that old patients have carcinomas of low grade. Study of carcinomas of the uterine cervix does furnish some data, especially concerning lesions of high grade, whereas the number of low grade lesions is relatively small for an analysis. In Table VI the ten-year age groups were arranged according to the grades of malignant change. When the percentages of distribution of age groups and grades are compared, there seem to be no outstanding differences. The distribution of ages compared equally throughout the table. Only 883 lesions of the total of 1,491 patients were graded, so an attempt was

made to determine whether the age distribution indicated in Table VI was representative of all the cases. In Table VII, the respective age groups are shown for both the graded cases and the total number of patients in the study. The similarity between the percentages of all cases and those of the graded cases in regard to their respective age groups should be noted; for example, the age group forty to forty-nine years, in which there were 496 patients (33.3 per cent) for all cases, whereas the number of cases in which lesions were graded in the same age group was 292 (33.1 per cent).

The data in this study show rather clearly that the age distribution and distribution of malignant change favor no special age group. The young and the old patient may have a carcinoma of low or high grade.

Technic of Treatment Employed

The radium technic employed at the clinic in the treatment of carcinoma of the uterine cervix may be defined as an intensive, multiple or broken-dose method.³ The radium or radon content of the universal tubes is in the range of 50 mg. or millicuries, respectively. The filters are kept constant. The only variables in the technic are the treatment time and the time between applications. The patient, however, represents an unlimited amount of variables. To vary the treatment time and the time between applications makes it possible for the radium therapist to treat his patient individually. The technic furnishes the widest distribution of the therapeutic energy throughout the field of the primary lesion. Another valuable attribute is that the primary field receives apparently adequate therapy, whereas the adjacent normal tissues receive the maximal radiation or the amount of radiation which they seem to tolerate. The primary lesion is treated with radium therapy as the initial procedure and roentgen-ray therapy is given as a supplemental treatment at the completion of the applications of radium. All patients, while treated and observed, are in the knee-chest position. The hospital stay is reduced to a minimum in that the plan necessitates that the patient remain at rest in bed only during the time of application. The number of days spent in the hospital varies from eight to ten, whereas the total time required for treatment varies

from four to five weeks on an average for patients whose disease is in stage 3.³

Briefly stated, an ideal technic for radium therapy is one that can be applied with very little or no risk to the patient and at the same time will adequately influence the primary lesion and, if possible, the adjacent metastatic deposits. The technic so briefly outlined previously is not at all perfect; however, it does approach the ideal technic as defined.

The Experience of the Radium Therapist

The experience of the radium therapist is a valuable contribution to the science and art of radium therapy. The skill and practical wisdom gained by personal knowledge based on study and repeated observation do become reflected in the immediate and late results obtained. His task is not a simple one; instead, it is exceedingly complex. For example, the surgeon speaks of surgical judgment and we respond immediately in that we appreciate in a measure the meaning that he wishes to convey. With the same feeling we may mention radiotherapeutic judgment. The patient must not only tolerate and overcome the effects of the therapeutic procedure employed but also the therapist must interpret, in a measure at least, the probable response which the patient will make to a given procedure in order to obtain an initial good result which will eventually affect the five-year survival rate.

The work of the radium therapist in the early years of development of the field was more than double that of the radium therapist of today. The early worker had to acquaint himself with the radium applicators and the pathologic lesion which the patient presented. After almost forty years of work in this relatively new field of therapy for carcinoma of the uterine cervix, several technics have been comparatively well standardized. However, as yet, no worker in our field has been able to standardize the patient. So every patient who presents herself for consideration is a challenge to the radium therapist. With the diagnosis, the gross character of the tumor, the patient's general health, and the proper selection, timing and spacing of applicators, the initial result may be very encouraging and it may exceed our expectations and endure for many years. No patient should receive more irradiation than that which is necessary to heal

the lesion under treatment. The adjacent tissues should receive no more exposure to the therapeutic rays than will be tolerated with safety.

In Table VIII the data of the fifteen-year period are divided into three periods of five years each. The irradiation technic employed in the first period showed 8.3 per cent as the incidence of cure for five years or more. The second and third periods gave equal incidences of cure, 34.9 and 34.7 per cent, respectively, for five years or more. The difference in incidence of cure of the first period and that of the second period is significant, and the chief factors that brought about such a change were a change in the therapeutic technic, a better appreciation of the radium applicators, a better understanding of the patient's response to treatment and a better distribution of the therapeutic rays in the field of treatment. Prior to 1923, all carcinomas of the uterine cervix received moderate voltage (135 kv.) roentgen therapy and beyond that date so-called high voltage (200 kv.) roentgen therapy was employed. It seems evident that, as our knowledge and experience increased, the incidence of cure for five years or more also increased, especially so, following the first five-year period.

Hospital Mortality

The hospital mortality for the entire group of 1,491 patients was 1 per cent.² There were fourteen deaths (Table II) in the stage 3 and 4 groups (1.4 per cent). In the stage 1 and 2 groups there were no deaths, whereas in the modified group (all stages) there was one death. The period of treatment and observation necessary for completion of the irradiation technic requires about five weeks. The actual hospital stay is about ten days. Every endeavor is made to keep the patients ambulatory between treatments. When one recalls that the major groups in this study are patients who had extensive lesions, with varying degrees of actual and potential serious complications, it is stimulating and highly encouraging to know that they can be effectively treated with so little risk.

Treatment for Recurrences

Recurrence of carcinoma of the uterine cervix, in a strict sense, is rare today, in that surgical therapy is not employed as it was years ago in the management of such cases. Some of the

TABLE VIII. CARCINOMA OF THE UTERINE CERVIX TREATED WITH IRRADIATION ALONE. RESULTS TABULATED ACCORDING TO PERIODS IN WHICH TREATMENT WAS GIVEN

Five-year groups inclusive	Patients treated	Patients traced	Lived five or more years after treatment

1925-1929	647	571	198	34.7
1915-1929	1,491	1,245 (83.5%)	363	29.1

*Percentage of traced cases.

patients included in this study did have major surgical procedures performed, as well as an initial course of irradiation therapy (in the main, elsewhere, however), and the majority evidently were treated with apparently insufficient surgical intervention and irradiation. The treatment did bring about what might be termed superficial healing and thus reduced the tendency toward hemorrhage, local ulceration and toxic absorption. This favorable influence was reflected in the comparatively favorable status of general health. In some, there was extensive radionecrosis, and in adjacent tissue active carcinoma was present. The treatment which they had received did change the actual gross appearance of the lesions and naturally did restrict the subsequent limited radium therapy employed here. This is the main reason why the cases are grouped separately and are termed "modified." These cases are deserving of a more adequate and complete analysis. As a rule, treatment for such a group is very tedious; for example, the radionecrotic tissue must be protected or shielded from further exposure while the adjacent active tissue is actively treated. The anatomic relationships are altered, making it difficult, and in some cases impossible, to locate the cervical canal and uterine cavity. In a consideration of these patients, one is tempted to evaluate the importance of sentiment in the treatment and consulting room. The relatives are very solicitous and are anxious that something further be done, in that they do not want hope taken from the patient. Every endeavor should be made to acquaint the relatives with the risk and ultimate guarded prognosis; if they are willing to share the responsibility, a limited treatment usually can be applied. At least, bleeding, odor and pain

*One patient died during the course of subsequent treatment, a hospital mortality of 0.2 per cent.

can be favorably influenced. It is surprising to know that members of this group have a chance to survive five years or more, especially the stage 3 and 4 groups.

The small number of cases (Table IX) in the stage 1 group no doubt accounts for the unusual incidence of five-year cures and more than five-year cures obtained. It may emphasize also the importance of a careful follow-up system, in that, when adequate therapy is applied to small regions in which a recurrence has occurred, the period of palliation may be substantially extended. As a rule, further palliation does occur in all cases. It is possible, for example, to arrest the infiltration into the anterior vaginal wall; thus, a vesicovaginal fistula may be prevented or at least its formation may be delayed sufficiently to be of minimal distress to the patient. This is equally true of the prevention of rectovaginal fistula and probably unilateral or bilateral hydronephrosis. In a selected number of cases in which fistulas were present, and after suitable treatment and an interval to allow the tissues to approach a normal status, surgical intervention was then done for the correction of the anatomic defects. Our early results have been very encouraging. Three in the stage 4 group survived. One assumption is possible, in that all of the cells which infiltrated the region were not actively malignant.

Evidently these patients with so-called recurring carcinoma do deserve our best efforts in that with limited treatment and medical and surgical care they have a chance of survival for five years or more, and in nearly all cases the period of palliation can be definitely lengthened.

Summary

No attempt has been made to exhaust the topic under consideration or the data this group of patients furnished, nor have definite conclusions been formulated. However, there are some interesting factors for analysis, although the statements made may be incorrect. The study of this group has advanced our knowledge of this disease and the patients treated today should receive superior therapy and a better result should be theirs when compared with those of previously treated patients. Naturally, the extent of the local and distant malignant lesions, the age of the patient and his general health or vigor are the most important factors which will definitely limit the survival rates over a period of five years or more. From the standpoint of the radium therapist, the method or technic which he employs and the completeness with which the initial radium therapy is applied, based on judgment and skill, have a definite bearing on the immediate result and ultimate prognosis. Careful consideration by the experienced therapeutic roentgenologist should be given to those patients who are to receive supplemental primary and subsequent roentgen therapy. Patients who have recurrent lesions should be treated with care and consideration, for they can be definitely benefited and some will survive for five years and longer. All concerned must coöperate to obtain the utmost in "cure" and palliation for patients who have carcinoma of the uterine cervix.

INHIBITION ILEUS*

E. A. HEIBERG, M.D., F.A.C.S.

Fergus Falls, Minnesota

THE main purpose of this paper is to review briefly the present day methods of treatment of paralytic or inhibition ileus. It is a very common surgical complication; yet it is often difficult to recognize early and to treat successfully.

This type of ileus is not due to any form of mechanical obstruction, but is due to either a change in the intestinal wall, or to interference with its nerve supply, resulting in an inhibition of normal intestinal movements and a functional inactivity of the bowel.

Etiology

Paralytic ileus is noted most often in the presence of peritonitis. Varying in duration and degree, it is seen following every intra-abdominal operation, but, fortunately, the distention, nausea and vomiting usually subside in eight to twenty-four hours, when the dilated gut begins to contract with the production of "gas pains." During the performance of a laparotomy, trauma, exposure of the bowel to air, and packs that are too hot or too cool are frequently factors in producing adynamic ileus. Several writers have noted that worried, apprehensive patients are somewhat prone to develop postoperative ileus. Penetrating abdominal wounds, the extravasation of blood, and mesenteric thrombosis are also etiologic factors. Paralytic ileus may be of nervous origin, as the result of injuries and diseases of the spinal cord, or fracture of the lower ribs or lead poisoning. It may be of toxic origin as in pneumonia, uremia, undulant fever, meningitis and empyema. And it may be reflex as noted in renal or gallbladder colic, torsion of an ovarian cyst, crushing of a testis or strangulation of the spermatic cord.

Pathology

A progressive dilatation of the bowel with a corresponding thinning of all the layers of the intestines is the only pathological change noted in early paralytic ileus. As a result of this distention, intestinal secretion is increased, while the venous stasis diminishes absorption from the

bowel, so that large amounts of stagnant toxic fluid collect in the gut. Swallowed air, fermentation and gas-producing organisms also play a part in increasing this distention. At first the bowel is normal in appearance, but the persistent venous stasis, produced by the extreme dilatation, causes it to become progressively lavender, purple, black and gangrenous. The intra-abdominal exudate may be serous, fibrinous or fibrinoplastic.

Signs and Symptoms

In paralytic ileus, the predominating sign is abdominal distention, which usually involves the entire bowel. The pain, if present, is not intermittent or colicky in character, but is described as being a continuous dull generalized abdominal ache. As the tympanites increases, the pylorus relaxes, permitting intestinal contents to regurgitate into the stomach, producing nausea and later vomiting. Respirations become rapid and shallow, due to the marked increase of intra-abdominal pressure. The pulse is rapid and thin. The patient appears to be alert and apprehensive at first, but gradually becomes drowsy, cyanotic, and comatose. Delirium often supervenes before death. Peristalsis is relatively or completely inhibited, resulting in a "silent abdomen." A scout film will show a gaseous distention of both the small and large bowel, fluid layers between the coils, fluid mirrors in which air is layered over fluid, and frequently a so-called "ladder pattern" is noted.

Treatment

Prophylactic treatment is extremely important in adynamic ileus. Preoperative care includes mental preparation of patient, because a "nervous," worried patient is more susceptible to stimulation of the sympathetics, with a resultant inhibition of peristalsis. Therefore the fears and apprehension of all such patients should be allayed as much as possible.

Cathartics should not be given before surgery. Alvarez has shown that, following purgation, there follows a period of inhibition of peristalsis.

In the operating room prophylaxis is very important. The intestines must be handled very

*Read at the annual meeting of the Northern Minnesota Medical Association, Detroit Lakes, Minn., September 8 and 9, 1939.

gently, they should be exposed to the air as little as possible, and blunt dissection should be avoided. Proper temperature of all moist laparotomy packs must be maintained; and careful hemostasis must obtain, because free blood in the abdominal cavity acts as a peritoneal irritant. Soresi and Brown, among others, advise dilating the anal sphincter before the patient leaves the operating room, to permit gas to escape freely from the rectum.

Postoperatively, all liquids by mouth should be withheld until nausea and vomiting have subsided. A common practice is the routine application of heat to the abdomen, by stupes or the use of a cradle equipped with electric bulbs, or short wave diathermy, until signs of ileus have subsided.

After establishing a diagnosis, morphine is a very useful drug, and may be used freely in paralytic ileus. We formerly believed that morphine "splinted" the bowel, but recent studies have definitely demonstrated that it increases its tone. Ochsner states, "Morphine should be administered liberally after operation (in the case of an adult, unless some contraindication exists, the patient should receive $\frac{1}{4}$ grain of morphine sulphate every four hours whether they complain of pain or not), because, as has been shown repeatedly both in the laboratory and the clinic, morphine increases the intestinal tone and does not inhibit the gut as is commonly thought."

If these preventive measures are unsuccessful, and paralytic ileus develops, prompt and energetic treatment is necessary.

1. To combat the dehydration, starvation and hypochloremia, saline and glucose solutions must be given intravenously. Hypertonic salt solutions are very useful not only to replace the chlorides that are lost, but also to stimulate peristalsis. Wangenstein states that, " $\frac{1}{10}$ to $\frac{1}{3}$ gram per kilo body weight may be safely injected. 75 to 100 cc. of a 15 per cent solution of sodium chloride is the usual dose for a person weighing 150 pounds."

Glucose solutions may also be given, by hypodermoclysis or intravenously. Ochsner and Gage report that they have demonstrated that glucose intravenously inhibits peristalsis, but that this effect is lost when sufficient insulin is given to "cover" the full amount of dextrose administered.

Sufficient fluids should be given to maintain a daily urinary output of 700 to 1,000 c.c.

2. Different drugs, used to stimulate intestinal activity, have been used with variable results. Chief among these are physostigmin (eserin), prostigmin, pitressin, choline and acetylcholine.

Physostigmin produces powerful contractions of the smooth muscle of the intestines, probably by stimulating the vagus. It must be used with considerable caution, however, because larger doses than 1/30 gr. hypodermically may produce central vasomotor paralysis, cardiac depression, dyspnea, myosis, drop in blood pressure and tetanic contraction of the gut.

Because of these undesirable side-effects, physostigmin has been supplanted to a great extent during the past few years by prostigmin, which is a white crystalline powder that forms a very stable solution. It is obtainable in two concentrations, a 1:4000 solution for prophylaxis, and a 1:2000 solution for treatment. The prophylactic dose is 1 c.c. of 1:4000 solution every six hours starting the day before surgery and continuing until the second or third day postoperative. The treatment dose is 1 c.c. of 1:2000 solution, repeated as necessary. Beck, in a report of 220 cases, reports that prostigmin has a marked effect upon the intestine without affecting the heart. Gaenssle reports that this drug has no unpleasant effect upon the heart. Saegesser and others also comment on the absence of by-effects.

Pitressin, which contains the pressor substance of the posterior lobe of the pituitary body, often gives satisfactory results in relieving intestinal distension. It is administered in 1 c.c. doses, repeated as indicated.

Choline and its derivative, acetylcholine, occur in animal and vegetable tissues and in some drugs, especially ergot. Their effect upon the intestine is similar to eserine.

Canney reports a cure in 75 per cent of his cases of postoperative ileus by the use of choline chloride. Abel advises intramuscular injections of acetylcholine in 0.1 gm. doses every two or three hours until gas is expelled.

3. Enterostomy. Until Wangenstein demonstrated the splendid results that can be obtained by the use of the indwelling nasal suction

catheter, enterostomy was generally considered the mainstay in the treatment of paralytic ileus. While this surgical method of draining the intestine has often been a life-saving measure, it is, as Wangensteen points out, "only of very limited value because only a short segment (of the bowel) on either side of the enterostomy catheter is evacuated by the tube." For this reason several surgeons have, in the past, advised performing multiple enterostomies. The present day concept of the comparative value of these two methods of intestinal drainage, is, I believe, aptly put by Jackson when he states "that in a general way an enterostomy is indicated in all cases of adynamic ileus requiring intestinal drainage, where for any reason nasal catheter suction cannot be employed, or results cannot be obtained by its use." In other words, the nasal suction apparatus has supplanted the enterostomy as the method of choice in draining the bowel in cases of paralytic ileus.

4. Spinal anesthesia. The splanchnic or sympathetic nerves, which act as inhibitors of the intestines, are blocked by spinal anesthesia. By shunting out the influence of the sympathetics, the motor nerves are unopposed and active peristalsis results. Since in paralytic ileus there is an overactivity of the sympathetic nervous system, it is highly desirable to block out its influence on the bowel. For this reason, spinal anesthesia is widely used in this type of ileus. Splanchnic analgesia is employed by some men, but, according to Brown, the technic is more difficult and likewise more dangerous. He advises using three-fifths the spinal anesthesia dose because that amount of anesthetic does not produce a great fall in blood pressure and is fairly safe when given below the first lumbar vertebra. It should be added that in combating this drop in blood pressure adrenalin or ephedrine should not be given because they stimulate the sympathetics and thus have a tendency to neutralize or offset the effect of spinal block. Therefore, intravenous saline or glucose should be given to counteract the fall in blood pressure.

5. Decompression by nasal suction catheter. In reviewing the literature on ileus of the past seven or eight years, it is interesting to note the influence that Wangensteen has exerted in the treatment of this condition in advocating the use of the inlying duodenal tube. When his first papers appeared describing this form of therapy,

contemporary writers were discussing the merits of single and multiple enterostomies, ileocolostomies, gastric lavage and various drugs. Since that time the use of the nasal suction apparatus as the method of choice in treating paralytic ileus has, in general, superseded all other forms of therapy. The value of its use in competent hands can best be pointed out by citing the experience of Wangensteen, who states that since 1931 when suction first began to be widely employed at the University of Minnesota Hospitals in the treatment of distention, no patient with paralytic ileus has been subjected to operation for its relief. The long double-lumened, balloon-tipped intubation tube, developed by Miller and Abbott in 1934, is a further advancement in the treatment of ileus by decompression. By means of this tube it is possible to decompress the entire small bowel.

Summary of Treatment

Prophylactic

1. Proper preoperative care, including mental preparation. Avoid the use of cathartics.
2. During a laparotomy avoid traumatizing the bowel and exposing it to air. Maintain good hemostasis.
3. After operation, withhold fluids by mouth until nausea and vomiting have subsided. Application of heat to abdomen is advantageous.
4. Proper sedation. Morphine is very useful. It increases the tone of the bowel and promotes intestinal activity.

Active Treatment

1. Prevent dehydration and starvation and maintain the body chemistry. Hypertonic saline solutions replace chlorides and stimulate peristalsis. Glucose solutions should be given intravenously, "covered" by insulin.
2. Drugs to stimulate activity of intestine should be used with discretion. Eserin is somewhat dangerous. Prostigmin and pitressin are probably most useful.
3. Enterostomy is seldom necessary.
4. Spinal anesthesia is often effective in promoting intestinal motility. When used, three-fifths the anesthetic dose is recommended. Intravenous glucose or saline, instead of adrenalin or ephedrine, should be given to combat the drop in blood pressure.
5. The nasal suction catheter is our mainstay in the treatment of paralytic ileus.

EPISIOTOMY

Description of a New Instrument for Presuture Method

JOHN T. LELAND, M.D.

Herman, Minnesota

The presuture method in episiotomy or the placement of sutures before episiotomy is performed, has long been advocated, but the technical difficulties involved have made the method unpopular. The need for further anesthesia for repair of an episiotomy results too often in the

cous membrane. As each suture is drawn through, it is cut, leaving long ends, the last one being double. With the sutures inserted and their ends grasped with forceps, the perineum is cut, the scissors following the groove of the instrument.

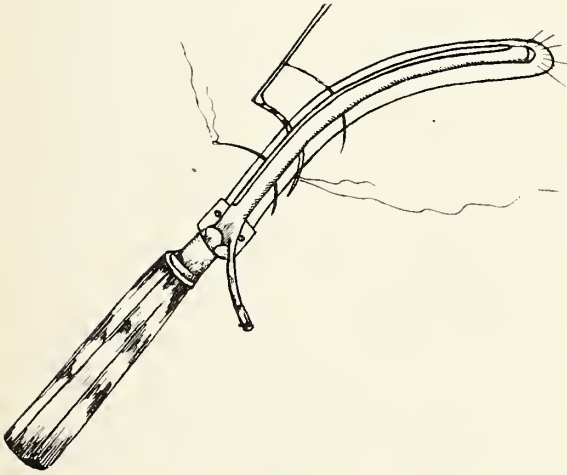

Fig. 1. Drawing of instrument, with electric attachment, showing relations of needles between tube and spatula.

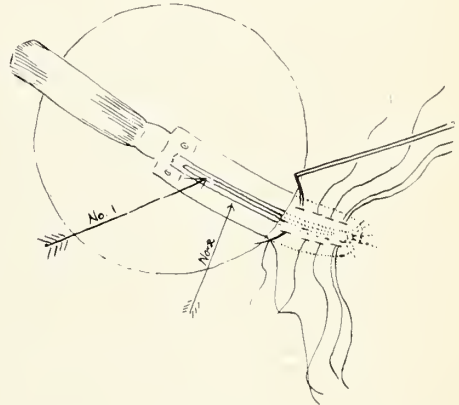

Fig. 2. Drawing of instrument, with battery in the handle, showing application. No. 1 is the groove along which the scissors are guided in making an incision. No. 2 is the tube attached at the proximal end under which the needle is passed.

omission of this valuable procedure. As an incentive for more general use of episiotomy by the general practitioner, who so often suffers from lack of trained assistants and proper illumination, an instrument is offered.

This instrument consists of a spatula-like blade, curved to conform to the infant's head, on the convex surface of which lies a curved rod attached only at the proximal end. The needle is directed underneath the rod, which is grooved for directing the scissors.

The instrument is inserted when the perineum is moderately distended at the time when episiotomy is indicated and pressure of the oncoming head or downward pressure by the operator produces an elevated outline, which facilitates the introduction of the sutures.

The sutures, threaded on a curved cutting needle carrier, are introduced through the intact perineum and beneath the tube, which acts as a guide, beginning at the junction of skin and mu-

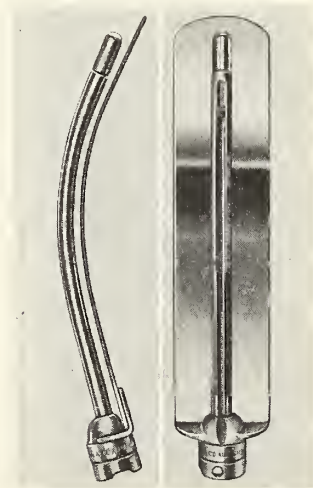

Fig. 3. Side and front views of the blade of the instrument.

The skin, urogenital septum, constrictor cunni, transversus perinei and some fibers of the puborectal portion of the levator ani are sev-

ered, resulting in a triangle-like incision with its base in a mid-lateral direction from the vulvar outlet.

In the final tying, the first or vagino-dermal stitch is used as a retractor while the depth of the incision is inspected. The deep muscles are approximated by an internal stitch, using one of the double strands previously inserted, which constitutes a "spare," carried where it is conveniently available. The stitches are now tied from below upward to complete the operation.

To remember that one's stitches are placed and held by forceps no matter what possible complication may be encountered is very consoling.

The instrument may be used without the services of an assistant. There is no need for

extending the anesthetic. There is no interference in the repair by untimely expulsion of the placenta. Time can be taken for resuscitation of the baby or meeting any other emergency, with the knowledge that the repair of the perineum only requires the tying of already placed sutures.

NOTE—The instrument has proven of value in cholecystectomy as a retractor and illuminator and in carrying a ligature. It is also of use as a retractor in inspecting the bed of the tonsil after a tonsillectomy.

The instrument is manufactured with battery in the handle,* in which case it is sterilized in lysol solution, wrapping the handle in a sterile towel; and with electric attachment, which instrument can be boiled.

*Manufactured by the Welch Allyn Company.

OCULAR TUBERCULOSIS—ITS SIMILARITY TO LEPROSY*

JOHN J. PRENDERGAST, M.D.
Saint Paul, Minnesota

THIS paper is not presented in order to stimulate undue interest in such a rare condition as ocular leprosy. Recently, I made a statistical study of leprosy of the eye under the sponsorship of the Public Health Service and I was struck with the apparent resemblance of the gross and microscopical ocular lesions to those of tuberculosis. Accordingly it is my aim to recapitulate our present-day knowledge of tuberculosis of the eye and call to mind its close relationship to leprosy.

Many writers have called attention to the similarity between the generalized lesions of leprosy and tuberculosis but, due to the comparatively few who have investigated the ocular lesions of leprosy, this analogy has not been seriously stressed.

The diagnosis of tuberculosis of the eye is still a much disputed question. We in this country, and especially in our section of the country, still emphasize focal infection as the cause of most of our doubtful and smouldering intra-ocular infections. This tendency, however, is much less today than it was twenty or thirty years ago, due largely to painstaking investigations by Ger-

man oculists and several in our country. Nevertheless, we are still puzzled as to why 50 per cent of uveitis cases in Austria and Germany should be diagnosed as tuberculous as against about 10 per cent in the United States. Kronfeld³ and Woods⁸ are of the opinion that many of the minimal roentgenological and physical lung findings in Germany would be considered normal by American internists. The universally accepted opinion, however, seems to be that ocular tuberculosis is secondary to some remote tuberculous foci which are usually located in the peribronchial glands and that the infection travels to the eye by means of the blood stream.

It would not seem necessary to call to mind all of the signs and symptoms of a tuberculous uveitis with which no doubt we are all familiar. Lloyd⁴ summarizes the principal features as:

1. Limitation of process to part of the eye involved.
2. Tolerance of the eye to the process without pain or undue redness.
3. Sharpness or insidiousness of onset.
4. Its chronicity and tendency to relapse.

Woods⁸ warns that we must consider:

1. The character and course of the eye lesion

*Read before the Minnesota Academy of Ophthalmology and Otolaryngology, Saint Paul, Minnesota, March 10, 1939.

and the correlation of this with other similar lesions previously shown to be tuberculous by histological examination.

2. The exclusion of other possible etiological factors.

3. A study of the general tuberculous status of the patient.

4. The reaction of the patient to tuberculin.

Many of us are no doubt guilty of occasionally disregarding these signs and precautions in attempting to diagnose ocular tuberculosis and attach entirely too much significance to the skin tests, in spite of the fact that we are aware that a positive reaction to more than .001 mg. of tuberculin means nothing, and even this positive reaction only signifies a previous tuberculous infection or rather "hypersensitivity" of that particular patient. Werdenberg,⁷ in his recent review of ocular tuberculosis, states that the diagnosis remains only "probable" as long as no tubercle bacilli have been found and the tuberculin test can be used only with reference to the general pathologic picture. It is generally recognized that the majority of patients, however, with a *clinically diagnosed* tuberculosis of the eye will react positive to .001 mg. of tuberculin. King of Boston in a recently read paper reported 70 per cent positives out of a series of 1,350 patients of this type. Friedenwald and Dessoff's¹ percentage of positives is slightly lower than this in their *clinically* and *histologically* diagnosed cases and they brought out the very interesting fact that between 40 and 47 per cent of this series failed to react to stronger dilutions than .001 mg. of tuberculin and thus resembled normals. We can therefore understand the need of a ratio between cutaneous and ocular sensitivity in tuberculin diagnosis and therapy as the only indicator we have, at present, is the cutaneous. There is and has been research work along this line lately.

In view of the unreliability of the diagnostic skin tests in tuberculosis, we are forced to look upon any smouldering recurrent and resistant eye condition as "possibly tuberculous" in origin; this, of course, after we have completed thorough foci investigation.

It might be well to mention here that "Purified Protein Derivative" of the tubercle bacillus, as isolated by Seibert⁵ and approved by the American Council on Tuberculosis, is at present being preferred by many men for diagnosis. Also that

the much recently publicized Gruskin² diagnostic test is being viewed with some skepticism by some of our local internists.

There are no diagnostic skin tests in ocular leprosy, but the diagnosis is easy as the disease has usually progressed for some time before the eye is attacked. Both tuberculosis and leprosy affect almost any portion of the eye or adnexa. Both are caused by remarkably similar acid-fast organisms. The leper bacillus is slightly longer and more slender than the tubercle bacilli and usually exhibits no beaded appearance).

These bacilli reach the eye by means of the blood stream through a bacillema which occurs at some time during the course of the disease. Tubercle bacilli might be hard to demonstrate in an eye lesion, but not so with leprosy, for thousands of them may be found in an ordinary sectioned cornea of leprous keratitis.

The Conjunctiva

Tuberculous and leprous involvement of the conjunctiva is rare. In an examination of 350 lepers I did not see a single involvement of the tarsal conjunctiva which I thought to be leprous. Tuberculosis of the tarsal conjunctiva usually occurs in the form of follicles or ulcers. These follicles, supposedly from movements of the lids, sometimes become elongated and pedunculated, thus producing the so-called "cock's comb excrescences." The ulcerative types sometimes result in polypoid formations. The bulbar conjunctiva also seems to be fairly immune from these diseases, except of course to participate in the underlying corneo-scleral involvement in both diseases.

Phlyctenulosis is usually primarily conjunctival and is thought to be closely allied to tuberculosis. Although no actual tubercle bacilli can be demonstrated in a phlyctenule, they are usually observed in persons with a tuberculous diathesis and are supposedly a response to tuberculin toxin.

The Cornea

The cornea is quite vulnerable to tuberculosis and leprosy, seemingly more so to the latter disease. It is almost always secondarily involved from the uveal tract. Deep infiltrations which usually emanate from above or from either side of the cornea, followed by an abundant mesh-work of vessels, form the most characteristic

lesion. Pannus formation is also very common in leprosy and the studded appearance of this change is fairly typical and diagnostic. Posterior precipitates are common in both conditions and the usual end-result is a sclerosing keratitis. Tubercle bacilli are not commonly found in these corneal infiltrates but leprosy bacilli are plentiful.

The Sclera

Although scleral involvement by tuberculosis and leprosy have a striking resemblance, the scleral tissue proper with its closely packed fibers in general offers stiff resistance to the invasion of these acid-fast organisms, and by far the greatest number of lesions are seen at the corneo-scleral margin and in the episcleral tissues.

In a series of twenty-eight sectioned lepers' eyes, which I examined recently, no bacilli were found in the deeper layers of the sclera. Of course, the avascularity of this tissue may be a factor here.

The Uveal Tract

As may be expected in a tissue with an abundant blood supply, tuberculous and leprosy involvement of the iris, ciliary body and choroid are quite common, and in most cases the uvea forms the starting point of the diseases. The clinical picture in the iris is quite similar. Usually there is very little or no pain, a negligible amount of pericorneal and stroma injection, some "K.P." spots and posterior synechiæ, and we may or may not observe tubercles or leprosy nodules in the stroma. Tuberculosis of the iris usually occurs in one of three forms.

(a) The usual chronic type in which one or several tubercles may be observed deep in the stroma, usually in the most vascular portions (pupillary or peripheral). Here we may also see "Koeppe bodies" at the pupillary fringe, which, although seen in this disease, contain no bacilli or giant cell systems and are thought by some to be an allergic manifestation like the phlyctenule, as their histologic appearance is quite similar.

(b) Miliary tuberculosis, in which small, gray, translucent tubercles exhibit themselves throughout the stroma, may be located deep or superficial.

(c) Conglomerate tuberculosis of the iris forms a large caseating mass usually coming from the angle of the anterior chamber. Types

"b" and "c" are not common. It is estimated that tubercles can be observed in about one-third of all iris tuberculosis.

Leprosy of the iris has a very insidious course and resembles the miliary form of tuberculosis in the later stages when numerous glistening white, pinpoint nodules collect on the surface of the iris, either uniformly or in clumps. However, these nodules, unlike tubercles, have a tendency to protrude from the surface and some may even seem to be pedunculated. There are many synechiæ. Proliferation of iris pigment and atrophy of the stroma, especially around the pupillary portion, is quite marked.

Tuberculosis and leprosy of the ciliary body consist principally of infiltrations in the anterior and stromal parts, especially around the ciliary major which eventually lead to caseation, perforation and atrophy. Verhoeff states that anterior segment tuberculosis results from bacilli being carried here by the aqueous and vitreous as a result of an inward rupture of a tubercle through the epithelial layers of the ciliary body. This may be true of leprosy also, but I believe that the wandering corneal cells carry the bacilli to the peripheral parts of the cornea and thence throughout the stroma.

The Choroid

When tuberculosis of the choroid occurs in the posterior segment, the solitary tubercle often resembles a neoplasm. It usually forms near vessels and at first consists only of round cells; as it grows, however, caseation and giant cells appear microscopically and the lesion pushes forward, thins the pigment and appears ophthalmoscopically. Military tuberculosis of the choroid is fairly rare. Leprosy choroiditis likewise seems to be uncommon, despite the fact that bacilli can often be seen extending back through the pars plana of the ciliary body into the choroid with the microscope. In a fundus examination of 243 lepers, only fourteen lesions of the choroid or retinochoroid were observed and many of these I did not think directly due to leprosy.

Retina and Optic Nerve

Retinal tuberculosis consists for the most part in an endophlebitis or periphlebitis of the retinal vessels, especially the veins, in which a tubercle may form in the vessel wall or outside the vessel wall to involve the adventitia. This

subsequently leads to thrombosis, organization or aneurysmal dilatations, which in turn form intra-ocular hemorrhages and retinitis proliferans.

Van Lint⁶ recently demonstrated the fragility of vessels in pulmonary and ocular tuberculosis by using the "cuff method" to cause petechiæ and strongly advised calcium and vitamins to prevent hemorrhage.

Many conflicting reports exist as to retinal lesions or hemorrhages in leprosy, but my conclusions were that they are very scarce. The optic nerve is practically immune to leprosy and tuberculosis.

Treatment

There is no recognized treatment for ocular leprosy, although many remedies have been tried. The usual systemic and hygienic pro-

cedures, coupled with the cautious use of tuberculin, offer the best results in tuberculosis. The actual administration and dosage of therapeutic tuberculin will not be discussed here other than to state that we usually prefer Denys bouillon filtrate. Werdenberg⁷ has stressed the value of high altitudes in conjunction with the other tuberculous therapy.

CONVULSIONS IN CHILDREN WHILE UNDER GENERAL ANESTHESIA*

Report of Case

O. S. WYATT, M.D.

Clinical Assistant Professor of Surgery, University of Minnesota
Minneapolis, Minnesota

THE increasing frequency with which convulsions under general anesthesia are occurring in children, elicits this case report and brief résumé of the subject.

In view of the fact that about 85 per cent of these cases occur in children and young adults, we, who work with children, must be particularly concerned. The first reports appeared in the literature about 1927, and since then they have been occurring with such frequency that this alarming phenomenon demands the attention of all anesthetists, pediatricists and surgeons.

Case Report

The patient, an eleven-year-old white boy in perfect health, was awakened about midnight, January 11, 1939, with pain in the abdomen. He was seen early the following morning by Dr. David Siperstein, who made a diagnosis of acute appendicitis.

At the hospital the laboratory findings were: urine normal, white blood cells 17,500, polymorphonuclears

96 per cent (about 50 per cent being band forms). His temperature was 102.4.

Past history was negative except for an attack of infantile paralysis in 1935 from which he made a perfect recovery. He had never had an abdominal attack of pain like this before.

Physical examination revealed no abnormalities except for the abdomen, which presented the signs of acute appendicitis.

Preoperative medication consisted of a hypodermic administration of morphine sulphate gr. $\frac{1}{8}$ and atropine sulphate gr. 1/300 at 7:30 a.m.

Anesthesia.—This was induced by nitrous oxide and maintained by ether administered by the drop method. While the child was being placed on the operating table the surgical supervisor remarked that the child felt much warmer than his temperature chart indicated. In retrospect, I suppose that his marked temperature elevation had already begun.

Operation.—The abdominal cavity was opened through a right rectus incision. No free fluid was present in the peritoneal cavity. The appendix was readily accessible and appeared acutely inflamed. It was removed in the usual manner with very little trauma. On section the lumen was filled with pus.

After the anesthesia had been in progress about 15 minutes the anesthetist reported slight cyanosis and

*Presented before the Northwestern Pediatric Society, Duluth, Minnesota, August 25, 1939.

observed twitchings of the eyelids. The pupils were dilated but reacted to light. On temporary withdrawal of the ether, the color returned to normal and the twitchings ceased.

The operation was completed without any further mishap, and the patient left the table with the usual postoperative appearance. The pulse during the operation ranged from 110 to 120. The operating time was thirty-five minutes.

The patient was returned to bed at 8:50 a.m. and appeared slightly cyanotic. His pulse was 150 and respirations thirty.

About twenty-five minutes after returning to bed the child had a terrific convulsion, became blue and presented marked carpo-pedal spasm. His temperature following the convulsion was 108.4. Heart sounds and respiration ceased during convulsion and never returned.

Etiology

Lundy reviewed the literature in 1937 and listed thirty-three causes which have been advanced to explain convulsions following anesthesia. A word regarding some of the more likely causes may be timely.

1. *Impurities in the Ether.*—The British investigators have been unable to prove this point. Ether impurities are: acetaldehyde, peroxides, ethyl sulphide, ketones, and alcohol. The first three are toxic if present to the extent of 0.5 per cent or more. They have analyzed the ether being used at the time of the convulsions on many occasions and have never found these impurities present in toxic doses. Woolmen and Taylor operated upon a child on a hot day, under open ether. A convulsion occurred and the anesthesia was discontinued. Following the convulsion, the anesthesia was continued with ether from the same bottle, with no further convulsions. They feel that ether, per se, or its impurities is not the cause of convulsions. They reported four cases in 1935, with a mortality of 50 per cent. They state that this condition is one of ether's most serious immediate dangers, but fortunately it is rare. However, I think we all agree that ether is by far the safest anesthesia in general use.

2. *Ether Convulsion Diathesis.*—Kemp suggested that there was such a thing as an "ether convulsion diathesis," maintaining that "if an individual develops tetany during an operation under anesthesia the same individual will again develop tetany if he is reoperated at a later date." Willway operated on a three-year-old child under ether who had convulsions but re-

covered. Forty-eight hours later when the child was more toxic he operated again under ether and no convulsions occurred.

The patient in this report had a tonsillectomy in 1936 under ether anesthesia with no untoward effects, and one is inclined to doubt Kemp's theory.

3. *Over-Etherization.*—Ashworth stated that in about 85 per cent of cases of ether convulsions the following factors are present: (1) the patient is under twenty years of age; (2) he is suffering from intense toxemia as a result of a septic local infection; and (3) the operating room is very hot. He maintains that the determining factor in the production of ether convulsions under these conditions is *deep* ether anesthesia.

Mennell, reporting eight cases, believed that over-etherization with over-oxygenation might be the cause. However, convulsions have occurred in cases where no oxygen has been used and in this case no oxygen was being used. This patient was in moderately deep ether anesthesia but the pupils still reacted to light.

Dr. Ralph Knight informs me that convulsions have occurred under every known general anesthesia. One case under cyclopropane is reported from the University of Minnesota.

4. *Excess of Carbon Dioxide in System.*—Pinson felt that this might be the cause. He reported fifteen cases with five deaths, all in children or young adults with acute infections.

Against this theory some British workers feel that carbon dioxide is the most effective agent in its treatment. Carbon dioxide not only removes ether from the body but also heat.

Seevers, Cassels and Becker, at the University of Wisconsin, working with rats, have shown the following:

	No. of rats	Convulsions or Twitch Per cent
Ether + pyrexia	24	0
Ether + CO ₂ (below 17%)	24	21
Ether + Pyrexia + CO ₂ (7-12%) ...	52	50
Ether + Pyrexia + CO ₂ (13-17%) ..	42	64

These authors have made clinical demonstrations which show that carbon dioxide given in sufficient concentrations will of itself cause convulsions.

Knight agrees with these workers and feels that carbon dioxide should never be used in the

treatment of convulsions, but that oxygen should be given freely.

5. *Anoxemia of Brain Due to Edema and Collapse of Lung Bases.*—Gwathmey feels that this may result from failure to use proper pre-anesthetic medication. It is true that edema of the lungs is the only constant post-mortem finding, but on the other hand we have been using morphine and atropine routinely as preoperative medication for many years and it is strange that no cases were reported before 1927.

6. *Atropine Over-Dosage.*—In many of the case histories that I have reviewed, a much larger dose of atropine has been used than is ordinarily given at our Children's Hospital.

I found in the literature instances of convulsions following anesthesia in which doses of from 1/150 to 1/75 grain of atropine were given children ranging from three to twelve years old. These are large doses of atropine and in these cases may have played a significant rôle in the convulsions.

Hornabrook, in criticizing Pinson, maintained that he was using too large doses of atropine in conjunction with ether. The ether, he maintained, was in no way to blame.

Hornabrook likewise reminds us that medical men fail to realize that the same dose of a drug cannot be given to a patient when under anesthesia as can be employed with possible safety in a patient who is not under that influence. He informs us that atropine is safer with chloroform than with ether.

Hornabrook, with thirty years' experience as an anesthetist, says that between five and twelve years of age the dose should be 1/12 gr. morphine and 1/200 gr. atropine; these doses mean safety. He states that the symptoms of atropine poisoning are "convulsions followed by paralysis, stupor at times, alternating with delirium, coma, and death preceded by heart failure and failure of respiration. Death is due to asphyxia."

7. *Acute Toxemia.*—MacKenzie feels that this is the essential and predisposing condition and that ether is the exciting agent. However, there are reports in the literature where a child suffering from acute toxemia developed convulsions during the first operation, and when operated a second time within a few days did not have convulsions.

8. *Heat.*—Woolmer and Taylor suggest that

ether upsets the normal heat regulating mechanism of the body and heat-stroke may play a big part in the etiology.

Willcox describes the hyperpyrexia from heat stroke as follows: "The onset may be sudden, with rapid rise of temperature, coma, and convulsions; the skin is hot and dry, face flushed and cyanosed; pupils dilated, fibrillary twitchings of the muscles and convulsions usually occur—pulmonary edema is a terminal event."

This description fits well with ether convulsions. All cases manifest hyperpyrexia. This boy immediately after his fatal convulsion had a temperature of 108.4.

9. Rosenow and Tovell suggest that this phenomenon may be due to a neurotoxin produced by streptococci which in the course of general anesthesia produce these convulsions.

Symptoms

The premonitory symptoms of this condition are always the same, and consequently should be a helpful guide in instituting early treatment.

Woolmer and Taylor reporting four cases in 1936 said, "The patient is a child or young adult with pyrexia, usually due to some septic condition. The theatre is over-heated. Atropine has been given and the dose may have been excessive. The patient is deeply anesthetized with ether, the pupils being dilated and inactive to light. The color is, as a rule, good and oxygenated ether is sometimes being given. The eyelids start to twitch, then the face, and the convulsions become general. In the immediately fatal cases after 5 to 10 minutes of convulsions, the respiration ceases, the patient goes blue, and the heart stops; in other cases, the convulsions stop, but the patient dies later from cardiac failure; alternatively, recovery may follow the cessation of convulsions."

In the non-fatal cases there is a tendency for the convulsions to cease in fifteen to twenty minutes. After the patient has returned to bed there may be a continuance of convulsions.

Treatment

The etiology of this phenomenon is certainly far from being settled; however, from the work that has been done, and a study of the literature, it is apparent that certain procedures are available to anesthetists and surgeons which, when properly used, may prevent a catastrophe.

CONVULSIONS IN CHILDREN—WYATT

TABLE I. SUGGESTED PRE-OPERATIVE MEDICATION

Age	Morphine	Atropine
18-15	1/8 gr.	1/200 gr.
15-12	1/12 gr.	1/300 gr.
12-9	1/16 gr.	1/400 gr.
9-6	1/20 gr.	1/500 gr.
6-3	1/24 gr.	1/600 gr.

Since these fatalities are becoming more common it is probably advisable that a soluble barbiturate be at hand for instant use whenever a child is being operated upon for an acute septic process, under deep anesthesia. This substance should be given intravenously at once if the patient shows any twitchings of the eyelids or about the mouth.

Wright, for a twelve-year-old boy, gave 3 gr. of nembutal in 10 per cent solution intravenously slowly, and convulsions ceased abruptly.

Knight believes that a short-acting barbiturate such as evipal soluble or pentothal sodium should be given at first, and that if convulsions tend to recur, nembutal or sodium amytal can be used for sustained action.

The British surgeons have demonstrated that chloroform inhalations will frequently control the convulsions; hence a can of chloroform should be in every operating room when a child is being operated for an acute septic process.

Oxygen is present in every well equipped operating room, ready for instant use, and should be given at once.

Cold should be immediately applied to the body and ice over the carotid regions.

Jackson advocates use of calcium gluconate in one grain dosage to check hyperirritability of the nervous system.

Adrenalin, which is an antiallergic, should be given at once. Adrenalin also mobilizes the glycogen reserve.

Sears reported a case in which convulsions ceased coincident with intravenous injection of 50 per cent dextrose, and suggested that the condition might be associated with hypoglycemia in children.

Gwathmey feels that we must be more careful in our preoperative medication and anesthetic agent.

I feel that our dosage of atropine should be regulated more carefully, particularly in hot weather, in view of the fact that the British report most of their cases occurring in hot weather.

TABLE II. TABLE DEVISED BY B. C. LEECH, REGINA, SASK., CANADA

Age	Morphine	Hyoscin
Up to 6 mo.....		1/1200 gr.
6 mo.-1 yr.....		1/900 gr.
1-2 yrs.	1/40 gr.	1/600 gr.
2-4 yrs.	1/32 gr.	1/600 gr.
4-8 yrs.	1/20 gr.	1/450 gr.
8-12 yrs.	1/16 gr.	1/450 gr.
12-16 yrs.	1/12 gr.	1/300 gr.

To be given by hypodermic injection forty-five to thirty minutes preoperatively.

Discussion

I feel that in order to attain still higher levels of safety in our surgical work upon children we must give some critical thought to our preoperative medication, anesthetists, and anesthesia.

In considering preoperative medication perhaps some changes are necessary in order to attain greater safety. Atropine has been routine in preoperative medication for a good many years and has become almost as well established as morphine. We should at least give smaller doses of atropine and I'm not so sure but that it should be dropped from our preoperative preparation when we are operating upon children for an acute septic process. Many of us have seen atropine cause a sharp temperature rise in children and perhaps therefore make them more susceptible to convulsions. Haggard, in his experimental work, proved that a rise in body temperature lowers the alveolar CO₂ tension and reduces the amount of CO₂ in solution in the blood. Since realizing that atropine occasionally causes these disturbances I have stopped using it and our anesthetists report that it does not make the administration of ether any more difficult. As far as I can tell, the anesthesia is as smooth without the atropine as it is with it.

With the twitchings, severe carpo-pedal spasms, and convulsions that these children have, perhaps a calcium disturbance plays some rôle in this picture. I wonder if calcium gluconate should be given intravenously thirty to forty-five minutes preoperatively. Personally I intend to discontinue the use of atropine until further investigative work has been done regarding it in respect to convulsions while under general anesthesia.

I think we must all plead guilty to having paid too little attention to our anesthetist and the type

of anesthesia being used. Our anesthetist must be more than just an anesthetist. He or she must understand children, be skillful in the administration of anesthetics to children, and be able to handle any emergency that may arise during the course of the anesthesia.

Henderson, from his vast amount of research work on respiration, tells us that the first principle of anesthesia is that the depth should be maintained as nearly uniform as possible. Depth should be attained as quickly as possible and the stage of excitement be as short as possible.

The disturbance of the CO_2 capacity of the blood under ether anesthesia appears to be wholly dependent on disturbance of respiration. If the anesthesia is managed so that the respiration is but little increased, the lowering of the CO_2 content of the blood is slight. Ether hyperpnea, however, causes a very great reduction in the CO_2 content of the blood and danger of an alkalosis. Light etherization loses this influence when administered with sufficient CO_2 to maintain the alveolar CO_2 at a normal level.

The supply of oxygen has relatively little immediate influence upon respiration. The administration of pure oxygen never acts as a stimulant. CO_2 , on the other hand, is the normal stimulant and regulator of breathing.

In quoting these facts from Henderson's work on respiration I hope to call your attention to the growing importance of the work which is being done in the field of anesthesia and to re-

emphasize the important rôle that anesthetics play in our work with children.

I believe we must be cognizant of these advances if we are going to bring greater safety to our patients during surgical procedures.

Conclusions

1. Convulsions under ether anesthesia are so unexpected and terrifying that we must have a definite plan of treatment agreed upon between anesthetist and surgeon.

2. Check temperature before anesthesia is started.

3. Adrenalin must be given instantly.

4. Soluble barbiturate must be on hand for instant use, whenever a child is being operated for an acute septic process.

5. Ether anesthesia must be stopped at once on appearance of premonitory symptoms.

6. Chloroform, oxygen, and carbon-dioxide must be readily available.

7. Calcium gluconate or dextrose (50 per cent intravenously) may be necessary to stop convulsions.

I have taken the liberty of calling this condition to your attention because of the fact that this phenomenon is on the increase and every individual who has anything to do with operative conditions in children must be prepared to meet this emergency.

INFLAMMATORY DISEASE OF THE THYROID GLAND*

THOMAS O. YOUNG, M.D., F.A.C.S.

Duluth, Minnesota

INFLAMMATORY disease of the thyroid gland can be defined as the resulting change in glandular structure produced by the action of a chemical, mechanical, or infectious process. It is characterized by lymphocytic invasion, and connective tissue proliferation, as well as other variable factors. Medical literature is filled with many excellent works pertaining to the various types of inflammatory diseases of the thyroid and their multitudinous phases. Such conditions become interesting, primarily because of the in-

frequency of their occurrence, the outstanding difficulty in recognizing them clinically, and finally because of the distinctive histological findings.

A logical classification of these conditions, Table I, will divide them into two groups with entirely different etiological factors. The first group consists of those cases in which the etiological factor is of a specific nature, while in the second group the reverse is true. Specific inflammatory disease of the thyroid includes tuberculosis, syphilis, actinomycosis, and echinococcus. All of these conditions are extremely rare

*Read at the annual meeting of the Northern Minnesota Medical Association, Detroit Lakes, Minn., September 8 and 9, 1939.

TABLE I. INFLAMMATORY CONDITIONS OF THE THYROID GLAND.

Specific:

1. Tuberculosis
2. Syphilis
3. Actinomycosis
4. Echinococcus

Non-specific:

1. Thyroiditis:
 - A. Acute
 - a. Without abscess formation
 - b. With abscess formation
 - B. Chronic
2. Riedel's struma
3. Hashimoto's struma
4. Strumitis
5. Lymphocytosis and fibrosis (slight to moderate)

and proven cases are still reported in the literature according to the total number found and published. It is not within the scope of this paper to give these conditions detailed consideration, but rather to briefly mention them and state their outstanding characteristics.

Tuberculosis of the thyroid is rarely if ever diagnosed preoperatively. Usually there is no clinical evidence of tuberculosis elsewhere, though the type of thyroid associated with miliary tuberculosis should be mentioned. In the classical case there is usually a diffusely enlarged gland causing pressure symptoms and characterized by a hardness and firmness which at times may be almost stony in character. The ordinary symptoms of thyrotoxicosis are often present *i. e.*, nervousness, irritability, tachycardia, dyspnea, and loss of weight and strength. Pathological examination of the gland shows a diffuse fibrosis with tubercle and giant cell formation and round cell infiltration. Attention should be drawn to the fact that a considerable number of thyroid glands removed surgically show tubercle and giant cell formation without any evidence of tuberculosis elsewhere in the body. Most of these cases contain no demonstrable tubercle bacilli and cannot be considered as tuberculosis. Thyroidectomy in this group as well as in true tuberculosis serves to alleviate the symptoms from which the patient sought relief. Histological and bacteriological studies of the gland removed at operation are essential before a final diagnosis can be made.

Syphilis, causing localized symptoms in the thyroid, is very infrequent. It is quite generally conceded by some authors that the thyroid is more resistant to this infection than other tissues of the body. Involvement of the thyroid may be found associated with secondary manifestations

of the disease. It is characterized by a diffusely swollen, markedly congested, painful gland. The localized condition yields readily to the usual antiluetic treatment. Syphilis may be characterized by gumma in the thyroid both in early or late stages. Microscopically the gumma shows the usual necrotic center surrounded by fibrous tissue invaded with lymphocytes and rather rarely giant cells.

Actinomycosis and echinococcus cysts in the thyroid are mentioned only because of their extreme rarity. It is unusual for these to be found by an average medical practitioner during his span of life, and little in regard to them can be found among medical writings. The diagnosis is not made clinically but entirely from a pathologic standpoint.

The present study is primarily concerned with the non-specific types of inflammatory disease of the thyroid. These include acute thyroiditis, acute thyroiditis with abscess formation, chronic thyroiditis, Riedel's struma, Hashimoto's disease (struma lymphomatosa), chronic strumitis, and lastly the frequent microscopic finding in a large percentage of goiters removed in which a mild degree of connective tissue proliferation and lymphocytic invasion exists.

Acute thyroiditis without abscess formation frequently follows acute infections elsewhere in the body. Such conditions as abscessed teeth, acute tonsillitis, and acute upper respiratory tract infection being the most common. Tenderness and swelling of the thyroid is present and is accompanied occasionally by dysphagia and usually by low grade fever. McQuillan states that the involvement of the thyroid may be localized or diffuse. At some period during the acute process varied manifestations of low grade hyperthyroidism may develop with metabolisms ranging as high as +30. Usually this condition is self limited and treatment with rest, salicylates, iodine, and heat is sufficient to promote a gradual diminution in symptoms. However, if response to this treatment is lacking, partial thyroidectomy should be done. Occasional myxedema follows acute thyroiditis.

Acute thyroiditis with abscess formation is a considerably more difficult and delicate therapeutic problem. Hertzler emphasizes the "terrible viciousness" that this form may attain. It may occur either in a normal or goitrous gland and like the non-suppurative forms, it frequent-

ly follows acute infections elsewhere in the body. Treatment consists in adequate drainage through proper exposure as soon as the diagnosis can be established. A common error is the failure to establish adequate drainage which frequently necessitates further operation.

Chronic thyroiditis may be defined as an inflammatory process of low grade involving the thyroid gland. It is recognized usually post-operatively from a histological examination of the specimen removed. Culture of the specimen characteristically is negative and shows no bacterial invasion. In a study of 100 cases, Wallis divided them into three groups; (1) those having ordinary signs of goiter without thyrotoxicosis or inflammatory process; (2) those having low grade signs of inflammation such as recent swelling and tenderness; and (3) those where symptoms of thyrotoxicosis are predominant. There seems to be a definite predisposition in women as his series showed a predominance of 85 per cent. The pathological findings vary from a marked lymphocytic infiltration with connective tissue proliferation and destruction of thyroid follicles to the more moderate forms which may not be deemed of sufficient importance by the pathologist to be worthy of mention as thyroiditis. In these chronic types, the evidence points to an infectious or mechanical source as the etiological factor but, as stated previously, culture of the specimens is almost always negative. The treatment is essentially surgical, partial thyroidectomy being the operative procedure of choice. Hypothyroidism of varying degrees may result and is dependent both on the severity of the inflammatory process and the amount of thyroid tissue left intact by the operator. Eberts and Fitzgerald differentiate chronic infectious processes in the thyroid according to the presence or absence of goiter. When the lymphocytic infiltration involves one or more nodules, they feel that it should properly be called strumitis in contrast to thyroiditis which is found only in what was apparently a previously normal thyroid. The microscopic evidence of inflammatory process is essentially the same whether found in goitrous or non-goitrous tissue and its treatment the same. However, it is a quite generally accepted view that goiter predisposes to inflammatory conditions in the thyroid and that the susceptibility is definitely greater than that of the normal gland.

Granting that this conception of differentiation of the diagnoses is correct, then obviously many diagnoses of chronic thyroiditis which have been made should have been chronic strumitis.

In 1896, Riedel first reported in the literature two cases of unusually severe inflammatory disease of the thyroid, since known as Riedel's struma. The two cases reported showed extreme induration and fixation of the gland. At operation extra capsular extension, marked adhesions to surrounding structures, and actual infiltration of vessels was found. Since this time, other cases have been reported from time to time, but definite, pathologically proven cases still remain a rarity. In 1936, Lee reported ninety cases of proven Riedel's struma culled from the literature and commented on the differential diagnosis. The condition is usually found in young to middle aged adults, the sex about equally divided, though some authors feel that there is some predisposition to this condition in the female. About 35 per cent give a history of pre-existing goiter. The disease may be unilateral or bilateral, the region involved varying from the size of a pea to the entire thyroid and surrounding structures. Clinically, a diagnosis of malignancy is made in about 90 per cent of cases. Usually these cases are characterized by dysphagia, dysphonia, swelling, and tenderness, with occasional symptoms of mild hyperthyroidism. The average metabolism in the series reported by Eisen was +10. Treatment is universally surgical and has varied from biopsy to partial thyroidectomy though the latter should be done where possible. The color of the gland varies from yellow to gray to pink. A histological study shows infiltration with lymphocytes and marked connective tissue proliferation with hyalinization. Pseudo-giant cells are usually present and may frequently be seen ingesting colloid material. A marked destruction of acini is quite apparent. Relief from surgical treatment is quite constant but according to various authors hypothyroidism follows in from 20 to 40 per cent of cases.

In 1912, Hashimoto reported four cases of diffuse lymphocytic infiltration of the thyroid. This became known as struma lymphomatosa and was at first considered a stage or form of Riedel's struma. Recent writers on this subject, however, agree that this is not the case, and that it exists as a distinct clinical and pathological entity. Graham in 1937, established its in-

THYROID GLAND—YOUNG

dividuality by clearly differentiating the clinical and pathological findings. Briefly this condition is found 100 per cent in the female and in middle aged or old adults. It is always a bilateral diffuse involvement of the thyroid from

the literature available failed to show any attention to this type of chronic inflammatory condition. It may occur to varying degrees in normal glands, diffuse, or diffuse toxic goiters, and in nodular, or nodular toxic goiters. The gland of this type usually has a slight to moderate infiltration with lymphocytes and slight to moderate connective tissue proliferation. Associated with it are occasional colloid changes such as variation in staining qualities and various degrees of vacuolization. Pathologists' reports vary as to their recognition of this condition and as to the emphasis they place upon it. It is usually not present in sufficient amounts to be classified as a thyroiditis or strumitis, but rather as coin-

TABLE III. DETAIL REGARDING 26 CASES OF NON-SPECIFIC INFLAMMATORY DISEASE OF THE THYROID

	Acute Thyroiditis	Chronic Thyroiditis	Abscess	Riedel's Struma	Hashimoto's Struma
Average age	46.2	49	16.2	56	49
Males	1	4	2	1	0
Females	6	8	2	0	1
Acute infection preceding	3	0	1	0

Pain	2	3	4	1	1
Tenderness	2	3	4	1	0
Swelling	2	2	4	1	1
Pressure	2	3	3	1	0
Toxic symptoms	2	3	0	1	0

the onset. The duration of symptoms varies from one to two years, and about 20 per cent show evidence of hyperthyroidism. Seventy-five per cent of these cases develop hypothyroidism postoperatively and it is occasionally found before operation. In contrast to Riedel's struma there is no involvement of adjacent structures adding to the technical difficulties of the operation. Pathologically the most prominent feature is a diffuse lymphocytic infiltration with formation of lymphoid follicles having active germinal centers. There is also an increase in connective tissue which seems to be a replacement fibrosis. However, this is much less in quantity and more delicate in formation than in Riedel's struma. The acini show considerable degeneration and crowding out by the lymphocytic infiltration.

The last group which should be emphasized receives scanty consideration in the literature and is usually mentioned by pathologists only as an incidental finding. These cases are found in vast numbers in operative specimens diagnosed solely as some type of goiter. Careful search of

cidental and having no particular significance. The frequency of this finding in goiters where no clinical evidence of inflammatory process existed leads to speculation as to the possibility that this pathological evidence of low grade inflammation may be a primary causative factor

TABLE IV. PATHOLOGIC FINDINGS IN 16 CASES OF INFLAMMATION OF THE THYROID.

in bringing the patient to the point of seeking relief. It is difficult to offer definite proof that this low grade condition should assume more importance in our clinical and pathological analysis.

However, a follow-up of a considerable group of these cases revealed a high percentage of cures, indicating that a possible relationship existed between these findings and low grade toxicity.

It is the belief of the writer that pathologists

Hospital, the following terminology was agreed upon as conveying to the surgeon or internist a concise understandable diagnosis. For example, such a diagnosis might read: Nodular Goiter with Hyperplasia II, Lymphocytosis II,

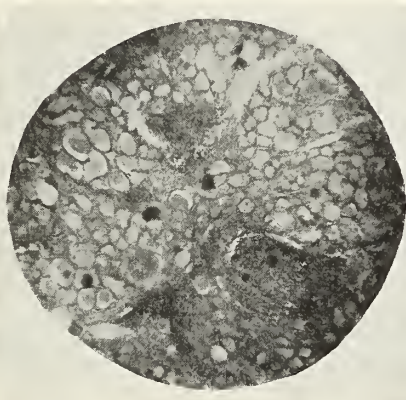

Fig. 1. Chronic thyroiditis showing marked connective tissue proliferation with hyalinization and extensive destruction of acini.

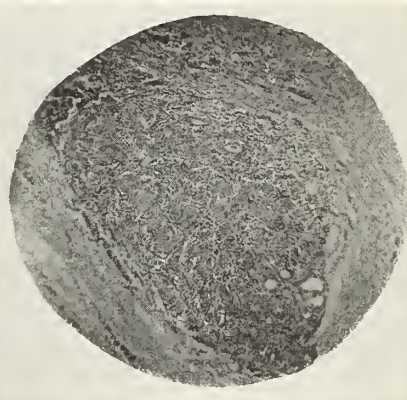

Fig. 2. Acute thyroiditis. Quite marked lymphocytic invasion with crowding out of thyroid follicles.

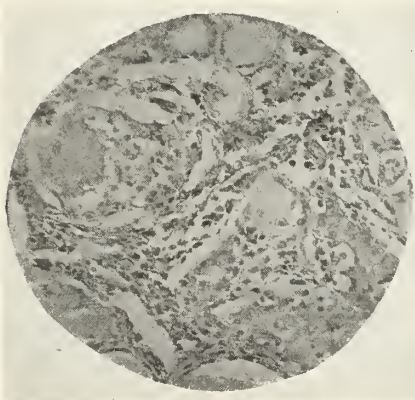

Fig. 3. Moderate degree of lymphocytic infiltration and connective tissue proliferation in low grade diffuse toxic goiter. This finding is quite universally disregarded.

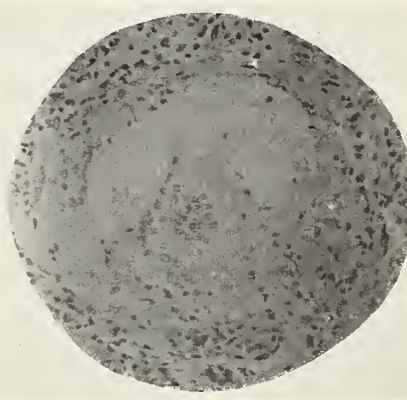

Fig. 4. Giant cell, ingesting colloid, surrounded by dense fibrous tissue.

should make a definite effort to include this finding in their report and that some term defining such a finding and having diagnostic significance should be used. Obviously they should not be called thyroiditis or strumitis, as these terms are applied to the more extensive and severe forms. The terminology used should be brief and to the point and convey a definite, understandable picture of the pathology found. Considerable thought and study have been given to devising a diagnostic terminology which would fill all the above qualifications. After discussion with Dr. Arthur H. Wells, pathologist at St. Luke's

Fibrosis I, or Diffuse Goiter with Hyperplasia IV, Lymphocytosis I, Fibrosis II. The value of the additional information conveyed should induce pathologists, surgeons, and internists to consider the advisability of using a uniform terminology of this or similar nature.

In addition to a review of the literature a study was made of all cases diagnosed as some form of inflammatory disease of the thyroid at St. Luke's and St. Mary's Hospitals during the past fifteen years. In this period 2,900 thyroidectomies were performed and out of this group only twenty-six cases or 0.8 per cent

were diagnosed as inflammatory lesions. In this series ten were diagnosed as chronic thyroiditis; seven, acute thyroiditis; four, abscess of the thyroid; one, tuberculosis of the thyroid; and one each of Riedel's and Hashimoto's struma.

plained of choking and two had fever. The pathological specimens both showed lymphocytosis and fibrosis, and one contained giant cells, tubercles, and showed epithelioid degeneration.

There were four cases of abscess of the

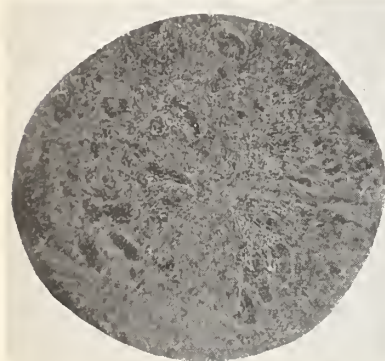

Fig. 5. Riedel's struma. Almost total destruction of thyroid acini by dense proliferating hyalinized connective tissue.

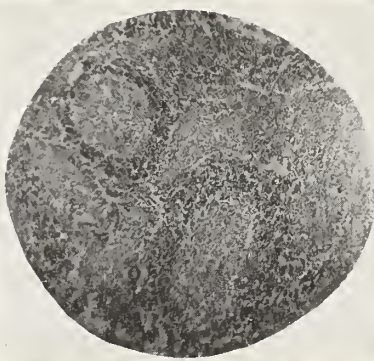

Fig. 6. Hashimoto's disease. Dense severe lymphocytic invasion with practically total obliteration of thyroid tissue. Formation of germinal centers is evident.

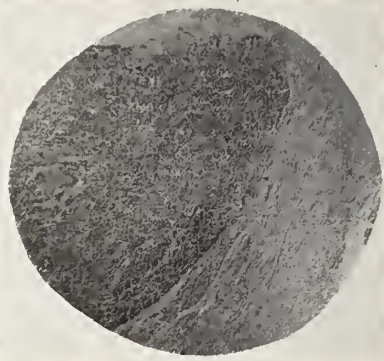

Fig. 7. Postmortem thyroid with total weight of 10 grams. Almost complete destruction of acini. Lymphocytic invasion. Connective tissue proliferation and deposit of fat globules.

There were seventeen females and nine males in the group. Sixteen patients were operated upon, two treated by x-ray, and the remainder were given medical treatment.

A brief résumé of the findings according to the type of pathologic lesions found was of interest. Of the twelve cases of chronic thyroiditis eight were females and four males with an average age of forty-nine. The average duration of symptoms, as was to be expected, was long and amounted to 195 days. In this group thyroidectomy was performed in eight cases, x-ray treatment in two, and two were treated medically. There was no history of preceding acute infection. The symptoms were quite evenly divided, the predominate ones being pain, pressure, tenderness, enlarged thyroid with mild symptoms of toxic goiter. Of the eight specimens removed all showed fibrosis and lymphocytic infiltration, three showed giant cell formation, and two definite destruction of the acini.

Seven cases were diagnosed as acute thyroiditis, six being females and one male. The average age was forty-six years and the duration of symptoms thirty-five days. An acute infectious process preceded the onset in three instances: one, impetigo; one, acute tonsillitis; and one, acute upper respiratory infection. The predominate symptoms were pain, swelling, and symptoms of thyrotoxicosis, while two com-

plained of choking and two had fever. The pathological specimens both showed lymphocytosis and fibrosis, and one contained giant cells, tubercles, and showed epithelioid degeneration. There were four cases of abscess of the thyroid: two male and two female with an average age of sixteen years. One patient had an abscessed tooth the week preceding. The average duration of symptoms was seven days while those most predominate were pain, tenderness, localized swelling and temperature. All cases were treated by incision and drainage followed by hot boric packs. One case was drained four times, one two, and the others one each.

There was one case of Riedel's struma in a male, aged fifty-six. Symptoms had been present for two months and consisted of hoarseness, difficulty in swallowing, definite diffuse enlargement of the neck, accompanied by symptoms of early thyrotoxicosis. At operation infiltration into surrounding structures was found to be present to a moderate degree. The specimen showed markedly severe connective tissue proliferation with hyalinization and destruction of acini. There were many atrophic follicles, and the presence of giant cells was noted.

The case of Hashimoto's struma (struma lymphomatosa) was a female, aged forty-nine, with symptoms of swelling of the neck, slight dysphagia, tenderness and pain present for about one year. The metabolism reading was —16. At operation a diffusely enlarged thyroid was removed without difficulty. The specimen showed moderate connective tissue proliferation,

marked lymphocytic infiltration throughout with germinal centers, giant cells and tremendous destruction of acini. The metabolism six months later had dropped to —36.

The case of tuberculosis in a male, age nine, was diagnosed by autopsy specimen in a patient dying from pulmonary tuberculosis. There was no suspicion before death that the thyroid was involved but pathological specimen showed giant cells, tubercles, and tubercle bacilli.

Another autopsy specimen is worth briefly reporting at this time. A male, age sixty-one, weighing 350 pounds, was brought to the hospital with acute heart failure and died in three hours. In this case the thyroid was removed in toto and weighed 10 grams. Microscopic sections showed marked acinar destruction and replacement with fibrous tissue and infiltrating lymphocytes. Only scraps of colloid could still be found. The additional meager data of tremendous weight, heart failure and undoubtedly marked hypothyroidism definitely classify this case as a severe chronic thyroiditis.

Conclusions.—A review of the literature and twenty-six cases of recognized inflammatory diseases of the thyroid emphasizes the infrequency with which such conditions occur and that the most successful treatment in the majority of cases is surgical. The importance of recognizing evidence of primary or secondary inflammatory processes of lesser degree occurring in all types of goiter is emphasized and a concise manner of reporting pathological diagnoses including these inflammatory changes suggested.

Summary

Twenty-six cases of inflammatory disease of the thyroid occurring in 2,900 consecutive thy-

roidectomies have been reviewed and important points of diagnosis emphasized. Sixteen of these patients were treated surgically, two by x-ray, and eight by medical management. Two autopsy specimens were included in the eight treated medically. Results in those treated surgically were good. There was a high percentage of hypothyroidism in this group, as was to be expected.

CRITICAL CREOSOTE CRITERIA

The report of the Council on Pharmacy and Chemistry of the American Medical Association (J.A.M.A., 110:209, Jan. 15, 1938) indicated that creosote and its allied preparations have received more promotion and widespread application in the past than is warranted by the available pharmacologic evidence. The Council therefore omitted all such preparations from New and Non-official Remedies because they are marketed without satisfactory evidence that they have sufficient therapeutic value and their use is based entirely on empiricism. E. J. Fellows, who previously reported three studies of a series, now reports a critical study of the effect of orally administered calcium creosotate on the twenty-four hour sputum of patients with pulmonary tuberculosis. In spite of the fact that estimations of the volatile phenols excreted in the urine of patients who received the highest oral doses of the drug indicated

adequate absorption, significant change in either the sputum phenols or sputum volumes was not observed in any of the cases during the period of calcium creosotate administration. The author also investigated the expired air of animals given the drug. Observations on six rabbits revealed that phenolic material was not present in their expired air during a period of eight to eighteen hours after each animal had been given 0.5 Gm. of water-soluble calcium creosotate phenols by stomach tube. The results of the entire study not only invalidate the reports of other workers who attempted to establish a rationale for creosote compounds in pulmonary disorders on the basis of change in the expired air during administration of such drugs but also disprove previous claims for symptomatic relief because of the increase in expectoration and appetite or lessening of cough. (J.A.M.A., Nov. 11, 1939, p. 1815.)

NASAL OBSTRUCTION: IS IT ALLERGIC?*

C. L. OPPEGAARD, M.D., F.A.C.S.

Crookston, Minnesota

THE ever widening field of medicine and surgery today makes it imperative for many to limit their knowledge to special regions of the body. Increasing application of this knowledge tends to enlarge the field of each specialty. This makes it necessary to have a more thorough understanding of phenomena which may have local manifestations, and in addition may affect remote regions of the body. This is never more true than in the field of allergy. No specialty is exempt from its capricious effects, and thus no specialist can afford to disregard its presence, but should acquire some knowledge of its etiology, diagnosis, and treatment. To the general man whose daily work touches upon all fields of medicine and surgery, it adds one more link to his ever widening horizon. The pendulum must not swing too far, however, for if it does, we may develop an allergic phobia which may prevent the proper treatment in a given surgical or medical case.

Affecting as it does every field of medicine, we, who limit ourselves to a specialty, feel justified in calling to your attention certain characteristics of this phenomenon as it affects our particular field, which may render clues to the proper treatment of corresponding conditions in other fields. The purpose of this paper is not to attempt to bring anything new into this already complex field of allergy, but to emphasize the fact that the cases of nasal obstruction you see may be allergic. The time is not far distant, we believe, when every case of nasal obstruction, either acute or chronic, should be declared guilty of allergic tendencies until proved innocent. This thought is not any more radical than the emphasis placed upon every bellyache as being one of an acute appendicitis until proved otherwise. For the purposes of this paper, when we refer to nasal obstruction, we mean to imply an obstruction of any degree and of sufficient moment to bring the patient to see you about its correction, or of sufficient moment to cause comment by the patient of its presence. When we refer

to allergy as it affects the nose, we are not referring just to seasonal hayfever, but to its many manifestations in the nasal structure.

The term allergy as used in the scientific sense is full of controversial meanings. As we are interested primarily in one clinical phase, we like the definition of the term as given by Ellis² in which he states that "allergy indicates a constitutional state whereby an individual reacts specifically and exhibits characteristic symptoms in response to substances which to normal individuals in like amounts are harmless and innocuous." Allergy and the term hypersensitiveness are used synonymously in clinical medicine, and rightly so, but they should not be confused with the term intolerance. The latter term, according to Ellis² "is used to designate the state or condition of an individual who responds to ordinary amounts of a substance in an exaggerated manner, but without characteristically different symptoms or physiological effects." To understand the reaction in allergic manifestations, the concept of the shock organ and shock tissue is necessary. It brings about a better understanding of the production of diverse conditions such as hayfever, asthma, eczema, urticaria, angioneurotic edema, allergic rhinitis, gastro-intestinal disturbances, and in many instances migraine, from contact with one and the same allergen. "Concerning shock tissue we have much to learn. That it is the same in anaphylaxis in animals and clinical allergy is extremely doubtful. In anaphylaxis, it appears to be chiefly, if not entirely, smooth muscle tissue—in the case of human allergy, the reaction in most of the major phenomena is almost always edema and not a result of smooth muscle contraction." "The anatomical location of the sensitized cells or shock tissues then determines the symptomatology of an allergic reaction."² If it is located in the nose, we will have manifestations of which hayfever is an example; if in the lungs, asthma; in the skin, eczema or urticaria, etc. Thus when we have symptoms referable to the nose, and of these symptoms nasal obstruction

*Read at the annual meeting of the Northern Minnesota Medical Association, Detroit Lakes, Minnesota, September 8, 1939.

is paramount, it is very important to determine with every means at our command whether the basis of the findings is due: (1) to the presence of shock tissue with its attendant reaction which we call allergic; (2) to an infectious agent; (3) to anatomical abnormalities; (4) to glandular or vitamin disturbances; or (5) to normal physiologic response to varying environmental changes.

It is important to emphasize some physiological facts concerning the nose as they relate to this symptom of nasal obstruction. Patients coming to you complaining of this symptom do not necessarily have pathological processes causing them. To many, the nose may or may not be a thing of beauty, but to all a well functioning nose is a blessing. It must have a perfectly adaptable mechanism, when you realize that it is the only organ of the body that cannot be adequately protected from the environmental surroundings in which it performs its functions. These are four-fold: to filter, to moisten, and to warm the inspired air, and lastly to smell. The efficient performance of these processes depends chiefly on the function of the vasomotor mechanism. What are some of the physiological responses of the nose which may be interpreted by the laity, and also by many doctors, as nasal obstruction? These are described fully by Lillie in a recent article.⁶ Briefly, allow me to indicate a few. We all know that the nasal cavity is divided by the septum, but we forget that it is scarcely ever straight. The importance then of a deviated septum lies in its effect on the nasal function. This was brought sharply to my attention quite early in my practice when, with the assuredness that comes only with recent completion of one's medical education, I would, after inspection of a nose with a bad deflection, state, "You must have considerable difficulty in breathing through your nose?" In the majority of cases the answer would be, "Not at all." Confidently, I would inspect another nose which, intranasally looked fairly normal, and then I would venture the statement, "Surely you have no trouble with your nose?" The answer would come back, "Doctor, I have a lot of trouble breathing. The nose is blocked most of the time." I soon learned to make my examinations with no comment, but would wait for a voluntary declaration from the patient. The point is, I was looking at the nose from an anatomical

standpoint, and not from a physiological one. Increased knowledge of the physiology of the nose in the last quarter of a century has now placed rhinology upon a more scientific basis. Many failures of intranasal operations can be traced to the fact that they were performed upon a strictly anatomic basis with no consequent relief of the patient's symptoms.

Another interesting point brought out by Lillie was the relationship of the erectile tissue of the nose and the sexual development of an individual.⁶ "It becomes clinically important that this be recognized, for it accounts for many of the so-called stuffy noses so often seen in adolescence and newly married couples." He also calls your attention to the effect of the climate and other atmospheric changes. "In the variable, rugged climate of the Northwest with frequent changes in the weather, one might expect that the membrane of the upper part of the respiratory tract would become hypertrophic, whereas, in the warm, equable climate, where the nose is not required to function excessively, there might be very little change." You are all familiar with the patient who complains at night of obstruction on the side on which he is lying. As Lillie states,⁶ this is due to passive congestion from gravity and is a normal condition. One must be sure, however, before one dismisses the patient, that this physiological evaluation of one's findings is not aggravated by some pathological process. Thus in one's final conclusion as regards normal physiological properties of the nose, let it not be said of you, "Some to the fascination of a name, Surrender judgment hoodwink'd."¹¹

Confronted with a case of nasal obstruction, we apply our reasoning so as to either convict the case as one of allergy, or by our findings find it non-allergic in origin. Proceeding in this manner, we have personally found that fewer mistakes are made in diagnoses. In some minor cases, the diagnosis is self-evident and detailed procedures are not necessary. However, you who feel that you have very few cases of allergy in your practice have overlooked them by not proceeding along an orderly manner in examination and diagnosis. In our limited experience, we can conservatively state that 30 per cent of our nasal cases seen in routine private practice have local findings attributable to allergy, or are associated with other manifestations of it. There-

fore to institute therapy on a rational basis, one should complete the clinical history, the physical examination, and laboratory procedures. As Faulkner³ states, it may seem advisable to take a preliminary history, then make an examination of the nose, and if there is found a suspicion of allergy, a more complete history can be taken. In any event, the clinical history must be thorough and complete. This cannot be stressed too strongly, for in many atypical cases a positive family history aids in the diagnosis, whereas the examination and laboratory procedures may fail us. As Hansel⁴ emphasizes, every possible relationship of the symptoms to the etiologic factors and to the possible association of other manifestations of allergy must be considered. Thus, first, the family history is all-important. He found in about 70 per cent or more of all cases there is a history of the occurrence of various manifestations of allergy in the family. This is the one true and common foundation all allergists stand upon: namely, the hereditary factor. Secondly, the association of other manifestations of allergy in the past and present must be analyzed. Hansel⁴ found this association in approximately 70 to 75 per cent of all cases of nasal allergy. Thirdly, the nasal symptoms, and particularly as regards this discussion the symptom of nasal obstruction with its associated manifestations, should be thoroughly considered from the following standpoint:

1. The time of onset should be exactly determined, if possible, so as to better associate the symptoms with possible contacts with the offending substances. The characteristic features of the onset with the effect of occupation, environment, seasons, drugs, foods, acute infections, and the physiological changes accompanying the different stages of life upon it, must also be considered.

2. The course and nature of the symptom of nasal obstruction as to whether it is constant or intermittent must be studied. Thus an analysis of acute exacerbations or periods of relief must be taken into account.

3. The relation of the symptom under discussion to the seasons, time of day, home or foreign environment, sports, occupation, foods, climate, physical agents, previous nose and throat treatments, either surgical or medical, and the effect of other diseases or illnesses must be

taken into consideration. This indicates briefly the type of clinical history that should be taken.

As the main characteristic reaction of allergy is edema, we should naturally expect to find on physical examination varying stages of that state in the typical cases. This can vary from the simplest sign of edema, indicated by pallor and intumescence of the mucosa, to marked hypertrophic thickening and polyposis. These changes can also occur in infections. Therefore aside from obstructions, physiologically or anatomically produced, the differentiation in most cases must be made between allergy and infection. Hansel⁴ states that with the exception of acute infections, allergy is the most common affection of the nose and paranasal sinuses. In typical cases, the symptoms and findings are so classical that the diagnosis is perfectly evident. In atypical cases, however, the symptoms may be intermittent, simulating recurring attacks of acute rhinitis. Therefore, other aids in diagnosis must be called upon. One of these is cytology of the nasal secretions. This procedure has been promoted so strongly of late that it has led many to disparage its importance, and has led them to remark that the diagnosis of allergy is dependent chiefly upon the findings of cytology. The true diagnostician regards the findings of cytology in the same light that the surgeon views an increased leukocytic response in the presence of an acute belly. In other words, it indicates that something is going on, and spurs investigation. We believe that there would be fewer mistakes made in diagnosis if the cytologic findings were taken at their face value rather than scoffed at or disregarded. Hansel⁴ is one of many authorities who consider it highly diagnostic. He states that wherever the lesion of allergy occurs, it is characterized by edema and eosinophilic infiltration. The eosinophiles are found in the secretions upon microscopic examination, even when there may be no visible evidence of edema. The presence of eosinophiles in significant numbers is absolute evidence of the allergic process, he states. A persistent absence of eosinophiles, except in cases of marked complicating sup-puration, definitely excludes the possibility of allergy. During acute infections, the secretions may contain only neutrophils and a few or no eosinophiles. As the infection subsides, the neutrophils gradually disappear and the eosinophiles gradually reappear in increasing numbers,

the secretions finally becoming clear and watery or mucoid. With marked nasal obstruction, secondary infection of the stagnation type may occur in which the secretions show a considerable number of neutrophils as well as eosinophils. Upon restoration of nasal respiration, the neutrophils quickly disappear. By repeated cytologic observations over a prolonged period of time, it is possible to determine the exact incidence of infections in the allergic individual, and also to indicate whether true allergy is present. In other words, one microscopic examination is not sufficient, but many should be performed. Nasal obstruction is rarely an emergency matter, so careful observation and examination should be the rule.

Having completed the history and physical examination with the laboratory procedures thus far indicated, the skin tests should next be performed. Again allow me to emphasize that too much importance has been placed upon them by the members on the outer fringe. They have exaggerated the importance of them and have said, just as they did in the case of the cytologic procedure, that the diagnosis of allergy is based on the skin test findings. Now these skin tests are not infallible. Many positive reactions can occur with no clinical proof, and in addition there may be many clinical manifestations of allergy with negative skin tests. However, the information obtained should always be correlated with the clinical history, the physical findings, and the other laboratory procedures. "In the final analysis of the relationship of positive skin reactions to the clinical sensitiveness, it should be determined whether the patient has contact with the suspected substances and whether upon contact the symptoms are produced."⁵

As further aids in diagnosis, we can but mention, due to the limitation of time, the bac-

teriologic and radiographic procedures, the elimination diets, and the effect of the allergenic treatment upon the given condition.

It has not been the purpose of this paper to present the diagnosis and treatment of allergic nasal obstruction, but its scope has been centered on the thought that every nasal obstruction should be considered allergic until proved otherwise. The methods of procedure to determine this have been indicated.

Conclusions

1. Every case of nasal obstruction, either acute or chronic, should be considered allergic in origin until proven otherwise.
2. The known physiological facts concerning nasal function should be remembered in every case of nasal obstruction.
3. With the exception of acute infections, allergy is the most common affection of the nose and paranasal sinuses. This is important to remember in treating nasal obstruction in children. It explains many poor results obtained from tonsillectomy and adenoidectomy.
4. In investigating a case of nasal obstruction, the history, and physical examination with laboratory aids are just as important in making the diagnosis as the skin tests, the bacteriologic and radiographic examinations.
5. Eosinophilia is indicative of allergy, but not absolute proof of its presence.

ABORTIFACIENT BARRED

On Jan. 21, 1939, Olaf M. Bornstad of Minneapolis was called on by the Post Office Department to show cause why the mails should not be closed to the "Bornocks Company," a trade style used by Bornstad in advertising and selling through the mails "Bornock's Tablet Treatment" as a means of producing abortion. Bornstad solicited business "by the use of newspaper advertisements" and letters. Mr. Bornstad waived a

hearing and indicated a willingness to have all mail addressed to his company returned to senders. On Feb. 15, 1939, the mails were closed to the Bornock's Company, and its officers and agents as such, because the business was a violation of statutes prohibiting the advertising and sale through the mails of any matter to be used for the purpose of producing abortion. (J.A. M.A., Oct. 21, 1939, p. 1583.)

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF MEDICINE IN HENNEPIN COUNTY

BY A. S. HAMILTON, M.D.

(Continued from January issue)

Hahnemann Medical Society of Hennepin County

Tribune Directory, 1873-1874:

"The Homeopathic Society was organized a few months ago under the name of Hahnemann Medical Society of Hennepin County. The officers are: W. H. Leonard, President; T. R. Huntington, Secretary and Treasurer. Meetings the first Friday of every month in the office of Drs. Goodwin and Flanders."

The following note of the Homeopathic Society is from *Neill's History of Hennepin County*:

"The Hahnemann Medical Society of Hennepin County was organized September 16, 1872, and was the result of an informal meeting of the Homeopathic physicians of the city held in Dr. W. H. Leonard's office September second of that year. A constitution and by-laws were adopted and signed by Drs. D. M. Goodwin, W. H. Leonard, G. F. Flanders, T. S. Huntington, M. H. Wallens, and Petrus Nelson. Dr. Huntington died in March, 1873. * * * * In May, 1880, a plan for a free dispensary was begun which resulted in the Cottage Hospital."

The latter statement would seem to have been an error, since the Cottage Hospital was opened early in March, 1871, and was due largely to the efforts and energy of Bishop Knickerbocker of the Brotherhood of Gethsemane, aided by Dr. Ames.

Davison's Directory, 1874: President, W. H. Leonard; Vice-president, G. F. Flanders; Secretary and Treasurer, P. Nelson.

Campbell's Directory, 1875: President, P. L. Hatch; Treasurer and Secretary, G. F. Flanders; Censors, Goodwin and Leonard.

Campbell's and Davison's Directory, 1876: President, D. M. Goodwin; Treasurer and Secretary, P. Nelson; Censors, Goodwin and Leonard.

Campbell's and Davison's Directory, 1877-1878: Officers same as before.

1878-1879: Officers same as before.

1879-1880: President, W. H. Leonard; Secretary and Treasurer, Miss Hutchinson.

Davison's Directory, 1880-1881: President, A. A. Camp; Treasurer and Secretary, S. P. Sterrett.

Davison's Directory, 1881-1882: President, A. A. Camp; Vice-president, Mary L. Swain; Secretary and Treasurer, Adele S. Hutchinson.

1882-1883: Officers same as before.

With this year the lists cease in the directories until 1893, when I have a record of the Hennepin County Medical Society, but nothing further of the Homeopathic Society.

Minneapolis Hospitals

As the COTTAGE HOSPITAL was the first private hospital to be opened in the Falls Cities, a further word as to its organization and development may not be out of place. The following items are taken largely from the *Daily Tribune*:

Daily Tribune of January 22, 1871:

"Through the kindness of Dr. A. E. Ames, the physician of the Brotherhood of Gethsemane, a dispensary has been opened in Dayton's Block by the Brotherhood for supplying the deserving poor with medicine and advice gratis. We hope this is preparatory to the opening of a hospital, an institution much needed in our city."

On Friday, March 3, 1871, the *Tribune* printed an editorial on "The New City Hospital," emphasizing its need, and giving something of its history:

"To come back to Minneapolis, the Brotherhood of Gethsemane, a benevolent institution believing that the time has come when in a population like that of the two Falls cities some provision should be made for the sick and maimed destitute, have taken the first decisive steps to that end by assuming the responsibility for providing a building for the purpose and, reckoning thereafter upon the benevolent promptings of our citizens to sustain the undertaking, they ask for money and a good attendance at Dr. Ames' lecture."

Then follows "The Appeal of the Brotherhood of Gethsemane in behalf of the Cottage Hospital." They had already secured a matron and received \$500 to furnish the building, rented temporarily on Washington Avenue beyond Bassett's Creek. Donations were to be sent to Messrs. Mendenhall and Westfall.

On March 7, the *Tribune* printed a letter from Rev. Knickerbocker in reference to the hospital, extending thanks, and adding:

"And now permit me to say a few words about the future of such a hospital. An institution like this in a large and prosperous community like Minneapolis and Saint Anthony should not be permitted to remain long in a rented and uncomfortable building. The time is not far distant when a medical faculty and a medical school must be connected with the rising University of Minnesota. A hospital is indispensable for such a school. Why shall this not grow into something of the kind? * * * * *

On March 9, a letter from A. E. Ames appears saying that there will be no contagious diseases admitted to the hospital, as the city itself already has a pest-house outside the city limits.

The Sunday, March 19, edition of the *Tribune* gives the following items under the heading,

"The New Hospital"

"The work of furnishing and preparing the hospital has been so far perfected as to admit of the reception of patients. Our citizens have responded generously to the call for aid in the enterprise. Already many useful donations of furniture and provisions have been made. Some eight beds have been provided, besides a good part of the general furniture of the house. The Masonic order has furnished a room comfortably. The employees of the Milwaukee car and machine shops a room. The Nicollet House, St. Mark's Parish, the Ladies' Aid of Gethsemane Church, the Brotherhood of Gethsemane, a lady of the Brotherhood of Gethsemane, and the millers each contributed the means to furnish a bed. The druggists have furnished a generous supply of medicine, the liquor merchants the necessary liquors, whilst several individuals have given general pledges of assistance. These will all be acknowledged in detail later. The bedding is all new and made up by the Ladies' Aid Society of Gethsemane Church. The first patient was received into the hospital on Tuesday [March 14], an orphan lad, eighteen years of age, without friends, of German parentage. He had been a newsboy on the Pacific Railroad and had been taken sick in a boarding house

without means of support. He expressed great gratitude for the comforts and attention of the home. A second patient was received on Thursday [March 16]. He was a Swede who lost a leg recently on the Milwaukee Railroad and was brought from Mendota. He, too, was overjoyed to get where he could receive proper care and attention. The third patient was received on Friday, a Norwegian, taken down in a bawdy house with pneumonia. He was brought to the hospital in filth and rags and was cleaned and made comfortable.

"Thus is the hospital meeting a great want in the community. It will no doubt soon be filled. It has a capacity of four more beds, which should be furnished at once. The working men of Minneapolis will take an interest in this home and contribute liberally to its support. It is the small contributions of the many that are asked to sustain it. . . .

"The government of the hospital is entrusted to the following persons: Superintendent, Rev. D. B. Knickerbocker; matron, Mrs. Mary A. Everts; physician and surgeon, Dr. A. E. Ames, with Drs. Goodwin and Linn as consulting physicians and Drs. Hutchinson and Hill as consulting surgeons; Treasurer, W. H. Chamberlain; Secretary, S. B. Cowdery; Directors, W. H. Greene, H. P. Westfall and R. J. Mendenhall. . . .

"Private patients can be accommodated and can have their own physicians visit them when they wish, as may also any beneficiaries."

The *Tribune* of April 2 contains an editorial urging a larger building, and on April 6 is found a notice of the first death in the hospital. The report of the hospital for May was as follows: Seven males and one female admitted. Four discharged, and one died. A note was made that during Dr. Ames' absence in California, attending a medical society, Dr. Linn had discharged the duties of medical attendant to the hospital.

The *Tribune Directory* of 1874-1875 gives the medical officers of the Cottage Hospital as follows: Drs. E. Phillips, A. Ortman, W. H. Leonard, and C. W. Putnam, attending and visiting physicians.

In 1876 (Campbell and Davison's *Directory*) the medical staff consisted of Drs. Phillips, Ortman, Leonard and Putnam, and in 1877, Dr. A. A. Camp was added. The staff remained the same in 1878 and 1879, but, in 1880, was changed to the following: Drs. Dunsmoor, Spaulding, Leonard, Putnam, and Camp. The 1881 staff comprised Drs. Dunsmoor, Wells, Abbott, Hamilton, Lawrence, Leonard and Camp.

BETHANY HOME was founded by the Sisterhood of St. Bethany in 1875, "for helping the tempted, saving the fallen, and restoring erring women to the right life." Mrs. T. B. Walker, who was secretary and later president of the Sisterhood, related in a report given to the organization just before her death in 1916, how a few women had become "somewhat disturbed by what they considered an unjust judgment of the court in sending four women to the State Penitentiary for immoral lives without making any effort to bring their male associates to judgment for the same offences. An appeal to the Governor brought the answer that if the sentence was remitted there would be no place for these women to go except back into their former lives. A house was rented, a matron provided and the four women received. But they soon rebelled against their position and, with their Bibles under their arms, walked out of this strange new home and pawning their Bibles for whiskey, were gloriously drunk and in the hands of the police before the morning of their first night of liberty."

For several years unmarried mothers were not admitted, for the founders felt that the public woman and the misled girl could not be associated together without injury to both. But in the course of the years the policy of the board changed and a maternity hospital developed and grew into the present Harriet Walker Hospital, named for the founder who served on its board for forty-one years and was also the first president of the Northwestern Hospital Board.

The MINNEAPOLIS FREE DISPENSARY was founded in 1878 by Hon. C. A.

Pillsbury, Geo. A. Brackett, C. M. Loring, A. B. Barton and E. S. Jones. It was intended to meet the necessities of a large class of deserving poor, who, while in need of medical assistance, were yet not subjects for hospital care. It was located at 208 Second Street South, where it remained until 1882, when it was incorporated into and became a department of the Minnesota College Hospital just established on the East Side in the building formerly known as the Winslow House.

Until 1881 the Cottage Hospital, whose name was changed to St. Barnabas in 1884, would seem to have been the only general hospital in Minneapolis, but in that and the following year there was a regular epidemic of hospitals, that of Dr. A. A. Ames being the second in the city. The directory of 1882-1883 contains this list of such institutions:

"Ames, A. A., Private Hospital, 4th Ave. So. and Washington.

"Cottage of the Brotherhood of Gethsemane, Cor. 9th Ave. So. and 6th St.

"Minn. College—Dr. L. C. Mitchell, Superintendent.

"Sisters of Mercy, 6th St. Cor. 25th Ave. So.

"Homeopathic—A. L. Bausman, Secretary."

The MINNESOTA COLLEGE HOSPITAL was established in 1881 in the large stone building well known at the time as Macalester College, formerly the Winslow House, on the corner of Bank and Second Streets, Southeast. In 1883 it was said to have a capacity of three hundred beds and was in charge of an able corps of physicians and nurses under the general direction of the board of trustees.

A HOMEOPATHIC HOSPITAL had recently been organized in 1883, when Richard Olding Beard compiled a Handbook of Minneapolis. Some fifty patients could be accommodated at their temporary quarters at the corner of Ninth Street and Eighth Avenue South. Its Hahnemann ward of ten beds was supported by the ladies of the city and in charge of female physicians. "The main hospital is under the care of competent homeopathic physicians."

According to Dr. Beard's Handbook of 1883, the SISTERS' HOSPITAL at 2416 Sixth Street South, under the management of the Sisters of Mercy, had a medical staff appointed by the sisters and provided care for seventy-five patients.

The NORTHWESTERN HOSPITAL was opened November 20, 1882, in a small rented house on Fourth Avenue South and Twenty-fifth Street. The organization meeting was held at the Friends Meeting House and Mrs. T. B. Walker was made president. Within a year the hospital was moved to a large house on Clinton Avenue, purchased for about \$3,000, and in 1887 a new building was completed at Chicago Avenue and Twenty-seventh Street, on land donated by Hon. L. M. Stewart, and still occupied by the present hospital buildings.

The institution was established in 1882, for the treatment of women and children, with a staff composed wholly of women: Drs. Mary G. Hood, Mary S. Whetstone, with Dr. Emily Fifield as resident physician. The consulting staff consisted of Drs. A. W. Abbott, H. H. Kimball, S. S. Whetstone, S. F. Hance, C. L. Wells, and A. H. Lindley.

The signers of the articles of incorporation included Drs. Annie T. Hass, Lizzie R. Hass, Mary G. Hood, and Mary S. Whetstone, along with a group of nine women headed by Mrs. Harriet G. Walker.

MATER MISERICORDIA HOSPITAL. In 1882, Mother Joseph, a Sister of Mercy from New Orleans, who was conducting a school in Anoka, purchased a tract of land on the west bank of the Mississippi, known as Murphy's Grove, a favorite picnic ground for the residents of the nearby towns of Saint Anthony and Minneapolis. The large frame house, home of the Murphy family, was taken over

by Mother Joseph and her companion, Sister Antonia, and opened as the first Catholic hospital in Minneapolis, the Mater Misericordia Hospital. The project was abandoned after a few years and the property bought by Bishop Ireland who turned it over to the Sisters of St. Joseph, who later opened St. Mary's Hospital there.

MATERNITY HOSPITAL was established in 1886 by Dr. Martha G. Ripley when she cared for three indigent maternity cases in a home on Fifteenth Street South. During the first year of its existence, thirty-seven women and thirty-two children were admitted.

The CITY HOSPITAL was organized by a resolution of the City Council passed July 1, 1887. In 1920, the name was changed to Minneapolis General Hospital. The following doctors have served as superintendents since its was established:

Dr. J. H. Dunn.....	July 1, 1887—July 1, 1888
Dr. Chas. A. Chase	July 1, 1888—Feb. 20, 1893
Dr. Chas. G. Weston	Feb. 20, 1893—July 1, 1899
Dr. Wm. J. Byrnes.....	July 1, 1899—July 1, 1901
Dr. Henry S. Nelson	July 1, 1901—July 1, 1903
Dr. George E. Ricker.....	July 1, 1903—July 1, 1905
Dr. Emil H. Beckman.....	July 1, 1905—July 1, 1907
Dr. Ole Linjar	July 1, 1907—Dec. 11, 1907
Dr. Peter M. Holl.....	Dec. 11, 1907—May 17, 1909
Dr. Archa E. Wilcox.....	May 17, 1909—July 20, 1909
Dr. Herbert O. Collins.....	July 20, 1909—July 16, 1918
Dr. Harry A. Britton.....	July 16, 1918—Dec. 15, 1919
Dr. J. M. Neal.....	Dec. 15, 1919—Jan. 20, 1920
Dr. Walter E. List.....	Jan. 20, 1920—Oct. 1, 1930
Dr. Chas. E. Remy.....	Oct. 1, 1930—July 31, 1937
Dr. F. E. Harrington, Acting Superintendent.....	July 31, 1937—Dec. 31, 1938
Dr. D. W. Pollard, Acting Superintendent.....	Jan. 1, 1939—to date

ST. MARY'S HOSPITAL was founded in 1887 by the Sisters of St. Joseph of Corondelet. Sister St. John Ireland, Superior of Holy Angels Academy, Minneapolis, was sent out to investigate the property vacated by the Sisters of Mercy after their brief tenure as the Misericordia Hospital, and found the old Murphy house entirely empty except for two straw bonnets such as were worn by the Sisters from New Orleans. Shortly, linen and supplies for the new mission were gathered at the Holy Angels Academy and in October, 1887, St. Mary's Hospital began its work in the old frame house. It could house twenty patients who had to be carried up and down the stairs. The attic was a ward; operations were performed on the table in the Sisters' dining room; water and instruments were sterilized in the kitchen; the Sisters ate from the pantry shelves and went without service of kitchen stove on operating days.

In 1890, the cornerstone was laid for a new four-story brick building, increasing the capacity to about one hundred. The school of nursing was formally opened in 1900.

The following physicians were the first in attendance at St. Mary's Hospital: A. W. Abbott, J. W. Bell, J. P. Barber, C. M. Cannon, J. H. Dunn, F. A. Dunsmoor, G. G. Eitel, Wm. A. Hall, P. M. Hall, R. J. Hill, W. A. Jones, J. W. Little, A. C. McCollom, J. E. Moore, L. A. Nippert, W. E. Rochford, C. J. Spratt, W. A. Spring, H. B. Sweetser.

Dr. J. H. Dunn was the first chief of staff, and his successors have been Drs. H. B. Sweetser (fifteen years), A. S. Hamilton, J. F. Corbett, J. M. Hayes, Leo Murphy, J. E. Hynes, M. J. Lynch, and Willard White.

The LUTHERAN DEACONESS HOME and HOSPITAL (1412 East 24th Street) began November 1, 1888, with a twelve-bed capacity in a small house at Hennepin Avenue and 27th Street with two years free of any rental charge. It was incorporated August 17, 1889, with Rev. M. F. Gjertsen, Prof. G. Sverdrup, Prof. S. Oftedal, and Frederick Laws, M.D., as the first board of trustees.

In 1891, a house and two lots on 23rd Street and Fifteenth Avenue South were purchased for \$5,500. The house was remodeled at a cost of \$3,500 to accommodate twenty-eight patients. At the time of the typhoid fever epidemic in 1892, a smaller building, consisting of two nine-bed wards, was erected at a cost of \$1,800 for the exclusive care of typhoid patients. In 1897, an adjoining lot with house was purchased for \$1,800 and in 1900 another house and lot added at a cost of \$1,600. These buildings provided hospital beds and homes for the deaconesses until the present modern hospital was erected in 1910.

Drs. Frederick Laws, Knut Hoegh, Jakob Hvoslef, and P. A. Aurness were the first attending physicians. In 1900, the medical staff was organized, with Dr. Frederick Laws as Chief of Staff, whose members were Drs. Frederick Laws, Henry Cotton and P. M. Holl; the surgical staff, Drs. Jacob Hvoslef, P. A. Aurness, George Haggard, and C. G. Weston; and the consulting staff of Drs. A. W. Abbott, and J. E. Moore. Drs. K. O. Bendeke and W. A. Jones were specialists in eye, ear, nose and throat, and nervous and mental diseases, respectively.

ASBURY HOSPITAL was opened September 1, 1892, under the auspices of the deaconess organization of the Methodist church and through the efforts of Mrs. Sarah Harrison Knight, who continued as its superintendent until her death in 1928. Mrs. Knight founded the Rebecca M. Harrison Deaconess home in 1891 after the Northwestern Deaconess Home, of whose board of control she was a member, had been abandoned. The care of the sick charges of her deaconesses and the training of deaconess nurses necessitated a hospital organization. She purchased the entire capital stock of the Minnesota College Hospital, which included a building at the corner of Ninth Avenue and Sixth Street South, which had been used as a dispensary by the University of Minnesota, and opened a hospital of thirty-four beds. In the first two and a half years they had cared for 1,065 patients in the hospital and 5,226 in the free dispensary.

In February, 1895, a fire partially destroyed the hospital. The patients were removed without harm and housed in St. Barnabas Hospital until the damage of the fire was repaired and patients again received less than three months later. The subsequent chapters of new buildings at the corner of Elliot Avenue and Ninth Street South, of the lease to the Veterans' Bureau and of the present building at 916 East 15th Street, took place after the turn of the century and so do not belong in the present volume.

Among the doctors whose names appear in the early records are found: Dr. F. R. Woodard, who is said to have brought the first patient to the hospital, Drs. F. A. Dunsmoor, G. G. Eitel, J. Warren Little, H. M. Bracken, W. A. Jones, George Douglas Head, Louis A. Nippert, J. C. Litzenberg, Arthur Gillette, Wm. R. Murray, and Frank C. Todd.

(To be continued in March issue)

CASE REPORT

SULFAPYRIDINE IN THE TREATMENT OF STAPHYLOCOCCUS SEPTICEMIA

J. S. BLUMENTHAL, M.D.

Minneapolis, Minnesota

A REPORT of recovery in a disease as almost invariably fatal as staphylococcus septicemia is always of interest. The introduction of sulfanilamide and more recently sulfapyridine in infections of all kinds has resulted in recent reports of recovery in several cases of this type. Morris⁵ reports a case with four positive cultures of staphylococcus albus treated with antitoxin, transfusions and sulfanilamide; Thornhill, Swart, and Reel⁷ report two cases of staphylococcus aureus septicemia which recovered following use of sulfanilamide, transfusion and drainage of localized abscesses. Fenton¹ and Hodgkins¹ used sulfapyridine in staphylococcus aureus septicemia with an atypical clinical picture with good results. O'Brien and McCarthy⁶ report using sulfapyridine in a staphylococcus bacteremia following furunculosis with recovery, as does Maxwell⁴ in the same type of infection in a case of pneumonia. Goldberg and Sachs² used sulfapyridine with recovery in two cases of staphylococcus bacteremia. Long³ reports sterilization of the blood in three out of five patients with staphylococcus bacteremia.

The case now reported is that of a man, aged fifty-four, admitted to St. Andrews Hospital, April 2, 1939, with a history of having fever and headache of several hours' duration. He had had an upper respiratory infection for several days but with no serious symptoms and apparently no fever or cough. He had no other complaints on admission. His past history was negative except for a history of lues of ten years duration adequately treated. He had had an osteomyelitis of his right big toe, which had been amputated eight years ago with no complications thereafter. He is married and has a wife and four children living and well. He had noticed some incontinence the last year. Otherwise the past history was essentially negative.

Examination revealed a very sick patient who had no subjective symptoms and now said he felt fine. His temperature was 105° F. The only positive findings were failure of pupils to react to light and absent knee jerks. The prostate was apparently normal but there was a residual of 600 c.c. of urine. His hemoglobin was 56, r.b.c. 3,200,000, w.b.c. 10,350. Blood smears showed a shift to the left in polymorphonuclears with a differential of 92 per cent neutrophils, 7 monocytes, 1 eosinophile. His blood Wassermann was negative and Kline 2 plus. The urine showed albumin positive with 250 to 350 pus cells, 2 to 4 r.b.c. per field. Blood urea nitrogen was 14.1 mg. per 100 c.c. of

blood. Spinal puncture was entirely negative. Urine culture on April 6, 1939, showed a positive staphylococcus albus culture and blood cultures on April 13 and April 14 showed the same organisms. On the basis of these findings, the diagnoses were cord bladder, cystitis with staphylococcus albus septicemia.

An indwelling catheter was inserted and the bladder irrigated with potassium permanganate. Sulfanilamide in 6 gram daily doses was given but with no improvement and after six days sulfapyridine in 5 gram daily doses was substituted. On this therapy the temperature began to drop and the patient looked improved. His urine cleared up until on April 18, 1939, there were only 2 pus cells per field.

Transfusions of blood, 2,500 c.c. in all, were given on April 14, 17, 25, May 2, and 8. His leukocyte count had gradually dropped until it was 6,000 on May 4 but the sulfapyridine had been continued due to a still slightly septic temperature. On May 10, the patient was sent home in fairly good condition but with catheter still indwelling as he had difficulty in voiding. When it was removed, after a few weeks at home, the patient voided with no difficulty. The sulfapyridine was given for three weeks in gradually decreasing doses.

Comment.—A case is reported of staphylococcus albus bacteremia with cord bladder treated by sulfapyridine with recovery. It is, of course, questionable how much credit, in this case, should be given to the transfusions, which were primarily used to increase the red blood count and hemoglobin, and how much to the drug; but certain it is that since the use of sulfapyridine more cases of recovery in staphylococcus septicemia have been reported and in this patient definite improvement was manifest after its use and also after failure to improve on sulfanilamide.

President's Letter

ON February 24, the Annual Officers' Conference will be held in Saint Paul. Excepting the annual meeting of the State Medical Association this is the most important medical meeting held in our state; and in some respects this annual conference of county society officers stands out above the State Medical Association meeting. It is particularly important that the secretaries of the county and district medical societies attend, for they are the spark plugs that energize the societies. The president and other officers, the committee members and especially the committee chairmen each have an important part to play; but an active, tactful secretary can do more to keep a society active and useful than anyone else.

Reports will be given at this meeting on what is going on in other societies—county, state, and national. The relief situation in its innumerable ramifications will be discussed; the latest information as to what Washington proposes to do will be available. Although but little information has been given out as yet regarding a new Wagner Bill, we are told there is one in the offing.

Economic changes are in the forefront today, and it is no time for any physician, much less any society, to be indifferent. That the doctors in our country are realizing the dangers inherent in impending changes in our economic status is shown by the greatest increase in the A.M.A. membership in decades and also by the very generous support being given the new National Physicians' Committee for the Extension of Medical Service. These are heartening signs, but our efforts must continue, and we may be called upon for more strenuous work than ever.

BERTRAM S. ADAMS, M.D., President
Minnesota State Medical Association

SULFAPYRIDINE AND PNEUMONIA

THE numerous reports on the use of sulfapyridine in pneumococcic pneumonia have served to standardize to considerable extent the use of this new drug. While the drug is not without its drawbacks and the possibility of toxic manifestations of serious import must be ever kept in mind, the numerous reports of series of lobar pneumonia with mortality rates of less than 10 per cent from the use of sulfapyridine alone or in conjunction with serum indicate a great advance in the treatment of this disease.

The accepted treatment is now to begin the administration of sulfapyridine as soon as a diagnosis of lobar pneumonia is made. The same holds true of postoperative pneumonia, and even in bronchopneumonia, which may be due to the pneumococcus. Every effort should be made to determine the type of pneumococcus. Upon determination of the type there is good reason to administer serum, although in many cases the improvement by the time the type is determined may justify its omission. Smaller dosage of serum seems to be effective when given in conjunction with sulfapyridine.

The purpose in sulfapyridine therapy is to obtain the maximum effect on the pneumococcus in the shortest possible time and to maintain its inhibitory effect on the pneumococcus until the infection is overcome. The initial dosage should be large, 60 grains, or the first two doses 30 grains each at an interval of four hours, and then 15 grains every four hours, day and night. It is well to give the drug following nourishment to minimize the likelihood of nausea and vomiting, although these symptoms are due to an effect on the central nervous system rather than on the stomach direct. If a dose is vomited within an hour after taking, the dose should be repeated. Vomiting is a main drawback in the use of the drug, but ordinarily does not contra-indicate continuance of its use.

One may expect a marked drop in temperature and pulse in twelve to forty-eight hours. If there is no such response within two days, continuation of the drug is probably useless and the etiologic bacterium is probably not the pneumococcus, although some strains of this organism are probably more resistive to the drug than others and absorption of the drug and blood concentration is quite variable.

Because of the rare occurrence of severe toxic effects from the administration of this drug, daily check should be made of hemoglobin percentage, leukocyte count and kidneys, the presence of blood in the urine indicating kidney damage. Jaundice is sufficient indication for discontinuation of the drug. Cyanosis other than

that due to the disease is apparently no indication for stopping the medication.

Ureteral concretions have been reported following the administration of sulfapyridine, more especially following the use of large amounts, although rarely have they been reported following comparatively small doses. The stones are composed of acetylsulfapyridine, are not radio-opaque and probably mechanically produce the hematuria. They apparently disappear on cessation of the drug and fluid administration in large amounts.

Although lobar pneumonia in children is not as severe a disease as in adults, some of the reports of the use of sulfapyridine in these cases are unbelievable. The recommended dosage for infants under two years is 1.5 grains per pound of body weight the first day, and half this amount succeeding days. For those over two years of age the dosage of 1 grain per pound for the first twenty-four hours, and half the amount each day following, has been accompanied by admirable results. The tablets may be crushed and administered in cereal, apple sauce or fruit juices. There seems to be no advantage in prolonging medication for longer than a day following the crisis.

Attention has been called to the fact that crisis in pneumonia treated with sulfapyridine is not accompanied by the feeling of well-being usually experienced. The appearance of the chart rather than that of the patient is a better indication of the progress of the infection. There is reason to believe that resolution of the consolidated lung begins at an earlier date.

Newspaper publicity to the effect that this new drug is 100 per cent effective is to be deprecated. The drug is showing a marked reduction in mortality from pneumococcal pneumonia, but is doubtless not the last word in chemotherapy for this infection.

VIRUS RESEARCH AND ANIMAL EXPERIMENTATION

WITHIN the present decade an amazing amount of progress has been made in the field of the investigation of filterable virus diseases. That this has been possible is due to the discovery of the fact that only by animal inoculation could the course and effects of virus disease be studied and the facts proved. Until this was

determined to be the case much time and effort were expended in following the culture and staining procedures which are so essential in bacteriologic research but give no help whatever in the solution of virus disease problems. In the study of virus disease the culture tube has been supplanted by the living animal, as Francis so aptly stated in his recent article in MINNESOTA MEDICINE.

Here, then, we see one of the most important advances of recent times in a difficult and baffling field made by the utilization of methods which are unreservedly condemned by those who fanatically oppose all types of animal experimentation. Here is concrete proof of its value, in a large way, but it will not be accepted as conclusive evidence by those who choose to cherish their antagonism. The onward march of scientific medicine has always been beset by ignorance and bigotry but somehow or other it has always managed to keep going. It is not a very comforting matter for reflection that from the very beginning up to the immediate present every discovery of value has been made by not merely unravelling the inherent difficulties of a problem but against determined human opposition.

GILBERT COTTAM.

FARMER TO HIS SON

The Conservation Checks ain't out,
I hear they're on the way,
But guess there won't be much for beer
'Cause there's some bills to pay;
We've got to pay the grocer-man,
His terms are strictly cash,
If he's not paid right on the dot
We'll have to live on hash.

I think we'd better pay the guy
That sold us that there seed,
Or he might up and say, "No, sir!"
Right in our time of need;
I'd like to pay the doctor some,
Perhaps a buck or two
Upon account of long ago
Would keep him smiling through!

But then there is the station man,
Where we get gas and stuff,
He's apt to say, "No more, my man,
I've let you take enough."
And then there is the permanent
Your mother wants so bad . . .
For things like that we must pay cash;
Remember that, my lad!

But "Doc" will speed through snow and cold
To serve us when we call—
The thought that age has yellowed bills
Don't slow him up at all;
The other guys must all be paid,
Accounts kept up to date . . .
So till we get our next year's check
We'll let the doctor wait.

—EVELYN OSLUND.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association

W. F. Braasch, M.D., Chairman

MEDICINE AND PUBLIC OPINION

AS ONE reviews the political events of the past year as they affected the medical profession, one is impressed with the fact that our position today has definitely improved. Legislation favoring governmental control of medicine has been defeated, both in Congress and in the individual states. It is evident that intelligent public opinion questions whether medical care would be improved by governmental edict, and that the value of free initiative and independence of the physician is recognized.

Reaction Reassuring

The reaction of the press toward the judicial rebuff given federal prosecution of the American Medical Association in the courts was most assuring. It was a signal victory for organized medicine. Progress in this case since then also has been very satisfactory. The defeat of the Wagner Bill, and, of even greater importance, the recent criticism of the bill with admissions of its shortcomings by top-ranking federal officials, shows clearly that they fear the consequences of radical changes in medical care.

The haphazard methods of preparing legislation in the all-important field of Health are clearly illustrated by the Wagner Health Bill. This was emphasized in public hearings on the bill when representatives of organized medicine showed its many inconsistencies. That portion of public opinion which demanded some change in the distribution of the costs of medical care should be appeased by the serious efforts on the part of numerous state and county medical societies to solve this problem. It is generally admitted that compulsory health insurance is undesirable. Various plans of voluntary insurance are being given thorough trials and it is to be hoped that some feasible plan eventually will be evolved.

Swing to Conservatism

The platform recently announced by the American Medical Association adopts a liberal attitude toward these problems which should quiet accusations of reactionism. Then too, a noticeable swing of public opinion toward conservatism and a desire for financial economy have greatly reduced the chances for large congressional appropriations for health reform.—W. F. B.

SEEING EYE TO EYE WITH LEMKE

It is indeed heartening to find a distinguished layman seeing eye to eye with organized medicine in a mutual opposition to regimentation, standardization, bureaucracy and socialized medicine.

Physicians who chanced upon the February issue of a certain popular magazine were especially pleased, no doubt, to note that Congressman William Lemke of North Dakota is sturdily opposed to all four. At the same time it was a little disturbing to the physicians that Mr. Lemke should profess to find the evils of bureaucracy, regimentation and standardization residing in the voluntary democratic organization of physicians. Particularly when it is the physicians' organization which is generally recognized as one of the most potent agencies in opposition to all three in American life today. It was still more surprising that it should be Mr. Lemke who is thus expressing himself with regard to bureaucracy since Mr. Lemke is generally regarded as an exponent of the political philosophy which finds expression in more and more government bureaus.

Investigation Proposed

In any case, it is on the ground of its regimentation, standardization and bureaucratic domination of medical men that Mr. Lemke proposes a Congressional investigation of the American Medical Association in this article.

Of course, the American Medical Association and its members will not oppose a Congressional investigation; on the contrary they may welcome it as one excellent means of impressing upon the Congress and the American people the accomplishments, aims and ideals of the independent medical profession of the United States.

UNSUITED TO MINNESOTA

The President's plan for hospital building where hospital facilities are lacking will undoubtedly have the support and approval of physicians and hospital authorities, provided the building is limited to communities that stand in actual need.

A preliminary inquiry from Washington concerning needs in Minnesota would indicate, however, that Washington planners are not thinking in terms of Minnesota and its needs.

There are undoubtedly a few isolated communities in Minnesota that need hospitals. Small hospitals of fifteen or twenty beds would amply serve these communities.

Would Not Be Used

Experts have advised the government, however, that it is uneconomical to construct and operate hospitals of less than 50 bed capacity whereas it is clear to Minnesota experts that anything larger than twenty-bed institutions in these Minnesota communities would be wasted. The beds would not be used and could not be maintained.

In the tone of this inquiry as in most other government planning it is obvious that the planners are thinking in terms of the South with its large negro population and that any nation-wide plan adapted primarily to southern needs would be utterly unsuited to the sparsely settled regions of Minnesota.

Federal Support Might Be Sought

It should never be forgotten, either, in making plans for government hospitals, anywhere, that the community must pay for the upkeep. Most communities which are already unable to build a hospital will also find it difficult to support one. In that case the hospital will have to be maintained by the state.

Probably direction in state-maintained hospitals would be put in the hands of State Boards of Health and, in Minnesota, the direction and management would undoubtedly be admirable. Cer-

tainly it would be carried on in close coöperation with the Minnesota State Medical Association. In other states the story might be different and in some, no doubt, state support would be refused, altogether, and the hospitals would become federally built and supported institutions.

It was suggested from Washington that the new hospitals might become health centers and house the local county or community public health units. In Minnesota, again, such an arrangement should be entirely satisfactory. There is always the possibility, however, that the public health unit, itself, rather than the state board of health or the state or county medical society would supervise the hospital. Then trouble might arise.

Details Should Be Discussed

All of the details of support, management and supervision should certainly be thoroughly discussed before any hospital building program is undertaken.

"IN JUDGMENT"

[Monthly editorial prepared by the Medical Advisory Committee]

Today the American people sit in judgment on the good and evil works of the various professions. After spending thousands of dollars to educate a medical man, they attempt to break down his morale and try to dissipate that which is most dear to him—his personal interest in his personal clientele and that patient-doctor relationship with which nothing else can compare.

This interest is a duty and this relationship a privilege which, as one grows older in the practice of medicine, becomes more sacred. But there is also an obligation to the men in our profession, our professional brothers. Many of the older pioneers in our state fought for the honor of the individual members of the profession, feeling, as you and I should, that when anyone is assailed by slander the whole membership suffers.

Malpractice litigation in the main is essentially slander against the whole medical profession and makes it easy for the "I told you so's" to conform to the present day feeling that the medical man is not doing his duty to the citizens of the land, that the sick of this country do not have the best in medical care because of carelessness on the part of the doctor, and that reg-

COUNTY OFFICERS' MEETING

Hotel Saint Paul—Saturday, February 24, 1940

The annual County Officers' Meeting of the Minnesota State Medical Association is always of interest to large numbers of physicians who are not, strictly speaking, officers of county or district medical societies.

The program arranged for the 1940 meeting scheduled for Saturday, February 24, at the Saint Paul Hotel, is open to any member of the association. As usual, expenses of the secretary or an alternate representative from each society will be paid.

Frank discussion of the problem of expert medical testimony as it looks to a county attorney will be an important feature of the 1940 program. Mr. James A. Garrity of Moorhead will give this discussion under the title, "The Doctor in Court."

Among other guest speakers of particular in-

terest are Dr. C. M. Peterson of Chicago, secretary of the American Medical Association's Council on Industrial Health, who will talk on the work of his council; Dr. R. G. Leland, also of Chicago, director of the American Medical Association's Bureau of Medical Economics, who will talk about national plans for health legislation, and Mr. Walter Finke of St. Paul, director of the new Division of Social Welfare, who will discuss the new medical program of his division. The new program was, incidentally, drawn up with the aid of his medical advisory committee and approved by the Council.

Round table breakfast discussions on subjects of current importance to Minnesota physicians will open the day's sessions. Breakfasts will be served at 8:30 and will be open to all physicians.

The complete program follows:

PROGRAM

8:30 a.m.—Round Table Breakfasts

1. Vaccination and Immunization Campaigns
—L. R. CRITCHFIELD, M.D.

Discussion of Local Organization, Methods, Charges

2. Relations with the University Hospitals and State Institutions

GEORGE EARL, M.D.

Discussion of Admissions and Discharges as Related to Eligibility and Subsequent Coöperation with Local Physicians

3. Inter-Professional Relations

J. M. HAYES, M.D.

Discussion of Local Relations with Allied Groups Such as Dentists, Pharmacists, Lawyers

4. Proposed Legislation for a Federal Hospital Building Program

L. L. SOGGE, M.D.

Discussion of Needs in Minnesota, Population to be Served, Number of Beds, Administration and Control, Future Uses

5. Medical Relief Problems

W. A. COVENTRY, M.D.

Discussion of the Law Relating to Choice of Vendor, also of Fees for Indigent Cases, Farm Security Clients, Authorizations, Hospitalization

10:00 a.m.—General Session

Presiding Officer—B. B. SOUSTER, M.D., St. Paul
Survey on Methods of Handling Medical Relief in Minnesota: Report

—W. A. COVENTRY, M.D., Duluth

Rôle of the County Contact Committee in the New Social Welfare Program

—A. W. ADSON, M.D., Rochester

Extension of Group Hospital Service

—A. M. CALVIN, St. Paul

County Fracture Programs

—R. C. WEBB, M.D., Minneapolis

Industrial Health

—C. M. PETERSON, M.D., Chicago

The Doctor in Court

—JAMES A. GARRITY, Moorhead

12:00 m.—Luncheon

Presiding Officer—B. S. ADAMS, M.D., Hibbing
Medical Program of the Division of Social Welfare

—WALTER W. FINKE, St. Paul

National Health Program

—R. G. LELAND, M.D., Chicago

Continuation Study Courses

—W. A. O'BRIEN, M.D., Minneapolis

Public Health Discussions in County Medical Societies

—O. O. LARSEN, M.D., Detroit Lakes

Board of Health Program for 1940

—A. J. CHESLEY, M.D., Minneapolis

"IN JUDGMENT"

(Continued from Page 127)

ulations and laws must be passed to regiment the practice of medicine.

Undue criticism by any unthinking man is a despicable thing, especially when used to increase his own prestige at the expense of another. Certainly no one is so blind as he who cannot see that there will be a reflection on himself.

Your Medical Advisory Committee believes that a knowledge, not an abuse, of our responsibility to each other guarantees an abundance of satisfaction and will help in the moulding of public opinion to our way of thinking.—B.J.B.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

Saint Paul Abortinist Sentenced to Two-Year Prison Term

Re: State of Minnesota vs. Arthur N. Alexander.

On December 9, 1939, Arthur N. Alexander, forty-eight years of age, entered a plea of guilty in the District Court of Hennepin County, to an information charging him with the crime of abortion. Following a statement of the facts to the Court by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners, Alexander was sentenced by the Honorable Arthur W. Selover, Judge of the District Court, to a term of not to exceed two years at hard labor in the State Prison at Stillwater.

Alexander was arrested by the St. Paul Police Department at his residence at 78 North Smith Avenue on December 6, 1939, following the signing of a complaint against him by the husband of a 41-year-old Minneapolis woman upon whom Alexander performed a criminal abortion on November 21, 1939. Alexander had gone to the home of this woman in Minneapolis and offered to perform this abortion for a fee of \$25.00. He was given \$5.00 at the time, but the balance was not paid for the reason that the patient became seriously ill and was removed to the Minneapolis General Hospital. The matter was referred to the Women's Bureau of the Minneapolis Police Department with Alexander's arrest immediately following. Upon being arraigned in the Municipal Court, Alexander's case was continued and his bond fixed in the sum of \$5,000. He later decided to plead guilty with the above result.

Alexander formerly held a license to practice chiropody in the State of Minnesota. This license was revoked by the Minnesota State Board of Chiropody Examiners on September 19, 1935, at which time Alexander entered a plea of guilty in the District Court of Ramsey County to an information charging him with practicing healing without a basic science certificate. For that offense Alexander was sentenced to a term of one year in the Saint Paul Workhouse and placed on probation. Since that time, he told Judge Selover, he had worked as a clerk and as a salesman for summer resort property. Alexander has had numerous difficulties with the law, having been arrested in Saint Paul on eight occasions between 1933 and 1935, several of the charges against him being drunkenness. In the present case, Alexander thought he should be

placed on probation, but he was promptly told by Judge Selover that with his previous bad record, he did not deserve to be placed on probation, and accordingly was sentenced to the prison term. The investigation conducted in the current prosecution also disclosed that Alexander had performed a criminal abortion upon another Minneapolis girl for which he was paid the sum of \$45.00.

The Minnesota State Board of Medical Examiners wishes to acknowledge the very fine cooperation received in this case from the Women's Bureau of the Minneapolis Police Department, and particularly from Lieutenant Blanche Jones, head of the Bureau, and Mrs. Edith Evans, policewoman. Some splendid results have been achieved in Minneapolis in this class of cases, and a large portion of the credit is due to the very prompt and efficient investigations conducted by the Women's Bureau. It has been a pleasure for the Minnesota State Board of Medical Examiners to cooperate with that Department.

Unlicensed Physician Sentenced to 50-Day Jail Term at Slayton

Re: State of Minnesota vs. John G. Halland.

John G. Halland, forty-six years of age, who formerly was licensed to practice medicine in the State of Minnesota, was sentenced on November 29, 1939, by Justice of the Peace J. K. Campbell, at Slayton, Minnesota, to a term of 50 days in the County Jail, the sentence to be served in the County Jail of Cottonwood County. Judge Campbell found Halland "guilty of interfering with the rural schools of Murray County by frightening the teachers and inspecting school records without proper authority from the County Superintendent or the Commissioner of Education.

Halland graduated from the Medical School of the University of Minnesota, in 1919, with the degree of Bachelor of Medicine. His license as a physician was revoked by the Minnesota State Board of Medical Examiners in November, 1931, because of habitual indulgence in the use of drugs. Halland has not been licensed to practice medicine in Minnesota since that time. He has a long record of difficulties with the law dating back to 1925, when he served one year in jail at Santa Fe, New Mexico, for a violation of the Federal Narcotic Law. In 1927-1928 Halland served fourteen months in the Federal Penitentiary at Leavenworth for a similar offense committed at Denver, Colorado. In 1932, he served seventy days in the Minneapolis Workhouse. In September, 1933, he pleaded guilty in the District Court at Fergus Falls to an information charging him with the crime of practicing medicine without a license. He received a suspended sentence of six months at that time.

Minnesota Physicians Reprimanded for Failure to File Birth Certificates

Following repeated complaints from the Division of Vital Statistics of the Minnesota Department of Health that certain members of the medical profession in Minnesota were violating the laws of this State in reference to the filing of birth certificates, the Minnesota State Board of Medical Examiners ordered an investigation to be made to determine the facts and what steps are necessary to be taken to secure the cooperation of those physicians who repeatedly neglect, or refuse, to comply with those laws. That investigation disclosed that a small number of physicians have repeatedly failed to comply with the birth registration law and with no plausible explanation for their failure. At the November, 1939, meeting of the Minnesota State Board of Medical Examiners one physician was ordered to appear before the Board and explain his repeated failure to comply with those laws. The facts in that case indicate that it was necessary for the State Department

of Health to send him nine letters in a period of four years in their attempt to secure birth certificates in cases attended by that physician. In addition, a personal call had been made upon the physician by a representative of the State Department of Health and also by a representative of the State Board of Medical Examiners. Despite the leniency extended this physician he still had outstanding two birth certificates, one as far back as March, 1939, and another in June, 1939. In this case the physician was advised by the State Board of Medical Examiners that unless he complies with the law in the future, a citation will be issued requiring him to show cause why his license as a physician should not be suspended or revoked.

The investigation made by the Medical Board clearly shows that the State Department of Health has been extremely lenient with the medical profession in this problem. On the other hand, there is no good reason why it should be necessary for local registrars and the State Department of Health to spend a great deal of time and money securing birth certificates from the attending physicians. It is not the desire of the State Department of Health to be severe, nor unreasonable, in the enforcement of the laws pertaining to births, nevertheless, it is very apparent that the law must be enforced and that it is of extreme importance to the patient, to the child, to the public in general, and to governmental authorities, that these certificates be filed. The law itself is very simple; the pertinent portions thereof could be summarized as follows:

1. The law requires the physician or midwife attending the birth of any child to subscribe and file a birth certificate with the local registrar within five days after the birth of the child.
2. If no name has been given the child within that time, the attending physician or midwife shall deliver to the parents a blank for a supplemental report of the given name of the child.
3. The law also provides that when a certificate of birth is filed without the given or baptismal name the local registrar shall deliver to the parents a blank for a supplemental report of the name.
4. If the child is illegitimate the name, residence and other identifying details relating to the father cannot be entered in the birth certificate without the consent of the father.
5. The law also provides that any person who shall violate any of the provisions of the law shall be guilty of a misdemeanor and shall be punished by a fine of not more than \$100.00 or imprisoned in the county jail for not more than ninety days.

Most of the violations of this law on the part of the medical profession are occasioned by the failure of the attending physician to file the birth certificate within the statutory period. The great majority of the physicians in Minnesota file these birth certificates promptly and within the period provided by the law. It is the hope of the Minnesota State Board of Medical Examiners that those physicians who are violating this law will make it a point, in the future, to comply with it. Certain it is that further violations of the law will result in the suspension of the medical licenses of the physicians involved.

Ely "Rheumatism Doctor" Sentenced to Six-Months Jail Term

Re: State of Minnesota vs. J. F. Brown, alias William Brown.

On December 14, 1939, J. F. Brown, also known as William Brown, sixty-four years of age, of Ely, Minnesota, entered a plea of guilty before the Honorable Edward Freeman, Judge of the District Court of St. Louis County, at Virginia, Minnesota, to an information charging him with practicing healing without a

basic science certificate. After a statement of the facts to the Court by Mr. John Arko, Assistant County Attorney, Judge Freeman sentenced Brown to a term of six months on the St. Louis County Work Farm. Judge Freeman told Brown that, after he had served thirty days of the sentence, the Court would suspend the remaining five months and place Brown upon probation for one year, upon the condition that he absolutely refrain from practicing healing in any way, shape or manner.

Brown, a Negro, who gave his birthplace as San Antonio, Texas, was arrested on December 13, 1939, following an investigation by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners, which investigation disclosed that Brown had been representing himself as a rheumatism doctor and had been giving various medications to patients for which he charged sums ranging from \$1.00 to \$2.00 per treatment. He also attempted to give massage treatments and used a so-called sun lamp in connection with his work. Upon being questioned, Brown admitted that he had no medical training whatsoever, but that he had been employed for many years as a shoe shiner and pants presser. He stated that he had lived at Houghton, Michigan, for twenty years and had been on the Minnesota Iron Range once before in 1927, after which he lived, for a number of years, at Duluth. He stated that because of his inability to find any work he turned to the unlawful practice of medicine to make his living. Brown's patients were men employed in the iron mines. Upon being questioned concerning the source from which he obtained his various medicinal preparations, Brown replied that he bought them from one H. P. Clearwater, Ph.D. The pamphlet indicates that Clearwater is a licensed pharmacist in the State of Maine. This case again emphasizes the ease with which an unsuspecting public is victimized by unscrupulous individuals.

Minneapolis Naturopath Sentenced to 4-Year Prison Term for Abortion

Re: State of Minnesota vs. Thomas N. Visholm.

On January 15, 1940, Thomas N. Visholm, seventy-six years of age, was sentenced by the Honorable Frank E. Reed, Judge of the District Court of Hennepin County, to a term of not to exceed four years at hard labor in the State Prison at Stillwater, Minnesota. Visholm had previously pleaded guilty, on December 22, 1939, to an indictment charging him with the crime of abortion committed on or about December 14, 1939, at the defendant's combination office and residence at 2312 Humboldt Ave., South, Minneapolis. Following an investigation of the case by the Probation Office of Hennepin County, and a statement to the Court by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners, Judge Reed stayed the execution of the sentence and placed Visholm on probation for a period of five years, during which time Visholm will be subject to the rules and regulations of the Probation Officer, and, among other things, he is to absolutely refrain from practicing healing in any manner in the State of Minnesota.

Visholm was arrested following an investigation by the Women's Bureau of the Minneapolis Police Department of a report that a criminal abortion had been performed by him on an unmarried girl who resides at New Brighton. At the time of his arrest deputy sheriffs and police officers seized Visholm's surgical instruments and equipment used by him in the performing of criminal abortions. The girl who had been aborted was taken ill and removed to the Minneapolis General Hospital. She has recovered and has been discharged from the hospital. The girl stated that she paid Visholm \$50.00 for his services. Visholm stated that

◆ OF GENERAL INTEREST ◆

Dr. C. R. Chadbourne has disposed of his practice at Janesville and will move to Saint Paul, where he expects to continue his medical practice.

* * *

Dr. Clifford T. Wadd of Waseca has purchased the practice of Dr. C. R. Chadbourne in Janesville. Dr. Wadd is a graduate of the University of Minnesota and had practiced in association with Dr. O. J. Swenson at Waseca the past year and a half.

* * *

Dr. Everett B. Coulter, a former member of the staff of Minneapolis General Hospital, has opened offices in Madelia, Minnesota, for the general practice of medicine.

* * *

Dr. Gordon C. Edwards and family, formerly of Cokato, are now making their home in Saint Louis Park. Dr. Edwards has been granted a scholarship for a year's study at the University of Minnesota and later will enter public health work.

* * *

Dr. C. E. Johnson, who has been engaged in government work at Blackduck for some time, has returned to Pine River and will resume his medical practice there.

* * *

Dr. M. J. McMahon and family of Green Isle left early in January for New Orleans, where they will spend several months. Dr. McMahon will devote his time to taking a postgraduate course at Tulane University.

* * *

With the start of the new year, Dr. B. F. Osburn of International Falls turned over the operation of the Northern Minnesota hospital to Dr. C. C. Craig and Dr. R. H. Monahan and has retired from the active practice of medicine.

* * *

Dr. O. J. Johnson of Lyle has announced his association in practice with Dr. A. W. Allen at Austin. Dr. Johnson will continue his Lyle practice and will also continue to reside there.

* * *

Dr. J. A. Mason of International Falls, who has been associated in the practice of medicine with Dr. B. F. Osburn for four years, announces that he has established his own office in the First National Bank Building.

* * *

Oculists particularly are warned against the crooked tactics which have been used by a swindler, apparently for some time, on members of their specialty. The man is about forty-nine years old, approximately five feet ten inches and weighs about 155 pounds. He has light sandy hair, blue eyes and a ruddy complexion and is smooth shaven. His stunt is to be fitted for glasses and

then for payment presents a check, usually for \$30.00, asking for the difference in cash. He apparently gives the impression of being an honest farmer, for he has swindled oculists in Missouri and North Carolina.

* * *

Dr. Norbert J. Lilleberg has become associated with Dr. Lee W. Barry, with offices at 814 Lowry Medical Arts Building, Saint Paul, in the practice of obstetrics and gynecology.

* * *

Saint Joseph's Hospital, Saint Paul, has recently purchased 50 milligrams of radium for the use of members of its staff. A fee schedule comparable to those in use at the other hospitals in Saint Paul has been established.

* * *

Pneumonia Serum

Owing to lack of funds, free distribution of pneumococcic serum was limited to Type I and II beginning July 1, 1939. In November certain available federal funds made it possible again to provide specific serum for all the types of pneumococcic pneumonia and to continue the twenty-four-hour typing service.

* * *

The coöperation of American citizens is asked by the Bureau of Census of the Department of Commerce in its decennial census to be taken this year. The census will inquire into population, occupations, housing, agriculture and business in general. Answers to questions are required by law and are confidential. The Division of Vital Statistics in the Census Bureau is one of the important activities of the Bureau.

* * *

Dean Harold S. Diehl of the University of Minnesota Medical School has been appointed a member of the National Advisory Health Council of the United States Public Health Service. The primary function of this Council is to advise with the Surgeon-General concerning the scientific and research work of the Public Health Service.

* * *

Dr. Ruth E. Boynton, Director of the University of Minnesota Students' Health Service and Professor of Preventive Medicine and Public Health, has been elected as President of the American Student Health Association.

* * *

Dr. George L. Streeter, Director of the Carnegie Laboratories at the Johns Hopkins Hospital, Baltimore, visited the University of Minnesota Medical School on January 17 and 18. He lectured before the medical faculty and students on "Early Stages of Macaque Development and Their Significance in Primate Embryology."

* * *

Dr. Albert V. Stoesser, Associate Professor of Pediatrics, University of Minnesota, has received a grant-

IN MEMORIAM

in-aid from the John and Mary M. Markle Foundation in support of his studies on water and electrolyte metabolism in intractable asthma.

Dr. C. Meredith Guernsey, University of Minnesota, M.D. 1934, who has been associated with the division of surgery of the Mayo Clinic and Mayo Foundation since 1935, has recently moved to Chico, California, where he has taken over the position of Surgeon to the Chico Clinic and the Enloe Hospital.

Mrs. John Dwan has made a gift of \$5,000 to the Minnesota Medical Foundation for support of the program of the Human Serum Laboratory, which was established at the University of Minnesota Medical School in 1938. The Laboratory is administered by a committee including Dr. Irvine McQuarrie, Dr. Paul Dwan and Dr. Erling Platou as a research and service project on the use of human serum for the prevention and treatment of certain infectious diseases.

In Memoriam

Ernest H. Bohland

1874-1940

Dr. Ernest H. Bohland died suddenly at his home in Saint Paul, 144 North Lexington Parkway, January 10, 1940.

He was born in Saint Paul, October 12, 1874, attended the Saint Paul public schools and Macalester College prior to the study of medicine. He received his M.D. from the Hamline Medical School in 1903. Later, he did post-graduate work at Rush Medical School. He practiced at Hanover, Minnesota, for two years and then came to Saint Paul, where he maintained an office at Goodrich Avenue and West Seventh Street throughout his career. In addition, he had an office association with Drs. Goodrich, Dennis and Gilfillan, and later with Drs. Savage, Brand and Nichols. He was on the staffs of St. Joseph's, St. Luke's, the Miller and the Children's Hospitals. He belonged to the Odd Fellows, and was a member of the Parish of St. Luke's and of the University Club.

In 1909, he was married to Miss Laura Taillefer.

There were few sports in which Dr. Bohland did not take part. In his early days he was on the racing squad of the Minnesota Boat Club; in his college days he was active in track athletics and football, and later in life a devotee of golf. He did a good deal of bird shooting, deer hunting and fishing.

To those of us who knew him best, his outstanding characteristics were his integrity, honesty and sincerity of purpose.

Surviving him are his wife; a daughter, Mary; a

son, Taillefer; a brother, John A. Bohland; and three sisters, Mrs. James E. Orme, Miss Beatrice Bohland and Mrs. J. S. Sweitzer.

Charles Rasmi Christenson

1867-1940

Dr. C. R. Christenson of Starbuck, Minnesota, died January 14, 1940. Death was due to a perforated peptic ulcer.

Dr. Christenson was born at Portage, Wisconsin in 1867. He received his early education in Owatonna. After studying a year at the University of Minnesota he taught school for two years and then returned to the University of Minnesota where he received his M.D. degree in 1895. He spent the next year as interne at Saint Barnabas Hospital in Minneapolis.

After moving to Starbuck in 1896, Dr. Christenson on several occasions took postgraduate work in Chicago, Philadelphia and Boston. In 1914 he traveled abroad, visiting the Scandinavian countries and Germany.

In September, 1917, Dr. Christenson sold his equipment and moved to Morris where he remained until he entered the Army Medical Corps at the time of the World War. He was stationed at Battle Creek, Michigan. Following the war he returned to practice at Morris until 1922 when he returned to Starbuck. At various times he was a member of the school board, coroner, a member of the council and mayor of Starbuck.

In 1930 he moved to Minneapolis where he practiced until 1936. In 1936 he again returned to Starbuck.

Dr. Christenson was a member of the Minnesota State and American Medical Associations until 1936.

George A. Kohler

1863-1940

Dr. George A. Kohler, Minneapolis, died January 9, 1940, at the age of seventy-six.

Dr. Kohler was born at Long Lake in 1863 and moved to Watertown, where he received his early education. He was a graduate of the Northwestern University School of Pharmacy and the Illinois College of Pharmacy. After graduating from Hamline Medical College in 1900 he attended the Polyclinic of Chicago and took postgraduate work in Vienna. Upon returning he practiced his specialty of eye, ear, nose and throat in Minneapolis from 1900 until 1939.

Dr. Kohler was member emeritus of the Hennepin County Medical Society, the Minnesota State and American Medical Associations. He was a Master Mason of the Watertown Lodge, No. 50, A. F. and A. M., and was a member of the Darius Commandery No. 7, Knights Templar, and an honorary life member in the Zuhrah Temple of the Shrine. He was a member of the medical corps during the World War. He also had membership in the Minneapolis Athletic Club.

Dr. Kohler is survived by a daughter, Louise Kohler

IN MEMORIAM

Hackett, of Minneapolis, and a son, George A. Kohler, Jr., of Lansing, Michigan.

James McCrea

1863-1939

Dr. James McCrea of Fulda died at his home December 19, 1939, after an illness of several months. He was seventy-two years old and had practiced in Fulda fifty-three years.

Dr. McCrea was born at Franktown, Canada, September 25, 1863. He graduated from the Ottawa Normal School in 1885 and taught school in Canada for nine years before studying medicine at McGill University. There he received his medical degree in 1894. The same year he was licensed in Minnesota and South Dakota. He practiced for several months in Salem, South Dakota, and in 1895 went to West Concord, Minnesota, for six months.

On August 1, 1895, Dr. McCrea was married to Emma Schneider of Salem, South Dakota. Dr. and Mrs. McCrea moved to Fulda in March, 1896, and had lived there since that time.

Dr. McCrea had an extensive obstetrical practice and kept abreast of the times. His early practice was in the horse and buggy days when good roads were the exception. He was one of the incorporators of the Citizens State Bank and was active in its management since its incorporation in 1908.

Dr. McCrea was a member of the Southwestern Minnesota Medical Association, the Minnesota State and American Medical Associations.

Owen McKeon

1874-1940

Dr. Owen McKeon, Saint Paul, died at his home, January 4, 1940, on his sixty-eighth birthday, following a heart attack.

Dr. McKeon was born in Henderson, Minnesota, January 4, 1874. He received his medical degree from the Minneapolis College of Physicians and Surgeons in 1900 and received his state license the same year.

After practicing three years in Saint Michael, Minnesota, he moved to Saint Paul, where he continuously practiced his profession.

Dr. McKeon was a member of the Hibernians, Catholic Order of Foresters, Knights of Columbus and for many years a member of the Ramsey County Medical Society and the Minnesota State and American Medical Associations. He was much interested in Boy Scout activities.

Dr. McKeon is survived by his widow, one son, Frank J., of Saint Paul, and two daughters, Gertrude McKeon and Mrs. Phillip A. Delavan of Saint Paul. He also is survived by two brothers, Patrick of Saint Paul and Dr. Philip McKeon of New Richmond, Wisconsin.

Frederick H. Neher

1891-1939

Dr. Frederick H. Neher was born September 9, 1891, in the family home of his father, Frederick Neher, and mother, Anna Koepler Neher, on the West Side of the city of Saint Paul, Minnesota. He received his grade school education in St. Matthew's Parochial School on the West Side, following which he attended St. Thomas High School for four years. His first year of pre-medical work was taken at the University of Minnesota, after which he transferred to Marquette University in Milwaukee, where he received his Doctor of Medicine degree in 1915. He spent a year of internship at the City and County Hospital in Saint Paul, following which he associated himself with Dr. Herbert Davis until he entered the Army shortly after the United States entered the World War in the spring of 1917.

While associated with Dr. Herbert Davis he spent his mornings assisting Dr. Comstock with his surgery. During his service in the United States Army he served in the cavalry, spending a few months at Harvard University in orthopedics. Shortly after the Armistice was signed he was honorably discharged and returned to Saint Paul, renewing his association with Dr. Comstock. After a few years of this association he became an assistant to Dr. Frederick Schuldt of Saint Paul, later leaving Dr. Schuldt to become associated with Dr. Edgar Norris. This association was continued until Dr. Norris was forced to leave practice due to ill health. Following this he was associated with Dr. John Hochfilzer and Dr. H. J. Prendergast. In January, 1931, it was the writer's privilege to become associated with Doctors Neher and Hochfilzer and my association with Dr. Neher continued until his lamentable death.

On July 12, 1922, Dr. Frederick H. Neher was married to Cecelia Kilbane. This marriage was blessed with two offspring, Frederick Neher, Jr., aged fourteen, and James Neher, aged four.

On November 23, 1939, due to an injury sustained to a boil on his arm, he became the victim of a staphylococcus septicemia which necessitated his hospitalization on November 27, 1939, and caused his death on December 6, 1939.

During the many years of my association with Dr. Neher it was my privilege to understand and enjoy his very mellow humor and outspoken frankness in all matters. His jolly pantomime manner in narrating all stories was thoroughly enjoyed by the entire medical profession of this Association. As so tersely stated by a member of our Association, "Dr. Neher was truly more than a member of the medical profession, he was an institution in himself."

He was a member of the American Medical Association, the American College of Surgeons, Minnesota State Medical Association and the Ramsey County Medical Society. He also was a charter member of the Saint Paul Surgical Society and an active member of the Medical Forum in Saint Paul.

EUGENE SCOTT, M.D.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR FEBRUARY

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis (810 kilocycles or 370.2 meters) and Station WLB, University of Minnesota (760 kilocycles or 395 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

February 3—Cause of Dyspepsia

February 10—Peptic Ulcer

February 17—Cancer of Stomach

February 24—Periodontia

STATE MEETING

Plans are now being completed, according to the Committee on Scientific Assembly, for the Scientific Exhibit of the 87th Annual Meeting scheduled for April 22, 23, and 24 at the new Mayo Civic Auditorium in Rochester.

Members who have exhibits to submit for this section of the meeting are urged by committee members to communicate immediately with the State Office, 493 Lowry Medical Arts Building, Saint Paul.

There are still a few openings on the Scientific Cinema program, also for motion pictures. Any information about interesting new pictures will be welcomed by the committee.

Three-quarters of an hour each morning and afternoon have been set aside for viewing scientific and technical exhibits, the scientific cinema and demonstrations, and no other sessions whatever will be allowed to interfere during these hours. The splendid facilities available in the Arena of the fine new Auditorium are expected to contribute materially to this section of the program.

Members of the Mayo Clinic staff will stage the entire program for Monday, April 22, including regular scientific sessions, ten Round Table luncheons at the Rochester hotels and an Open House at night in the Arena. Music, entertainment and refreshments will be provided and exhibits will be open for inspection.

Programs for Tuesday and Wednesday, April 23 and 24, are reserved for other state and out-of-state speakers. There will be Round Table luncheons on these days, also, with guest speakers and Minnesota experts acting as leaders on both days. Programs for the general sessions are built around the following subjects: Fractures, Coronary Disease, Radiology, Pre-operative Care, Cancer of the Breast, Progressive Loss of Vision and Child Psychiatry. The last two subjects, scheduled for Wednesday afternoon, April 24, are of especial interest to teachers and school nurses as well as physicians and the final session, accordingly, will be

thrown open to these and other interested outside groups as a climax to the meeting.

The regular Association banquet will take place Tuesday night at the Rochester State Hospital.

Among the outstanding guest speakers who have already accepted invitations to speak at the meeting are: Drs. Paul Magnuson, Harry Mock and Fred L. Adair of Chicago; Bernard H. Nichols of Cleveland; John O. Bowers of Philadelphia and Russell L. Cecil of New York.

Members of the Women's Auxiliary of the Association will hold their annual gathering at the same time, joining with the physicians for the Monday night open house and the banquet.

WASHINGTON COUNTY SOCIETY

The regular monthly meeting of the Washington County Medical Society was held January 9 at the usual time in the Stillwater Club rooms. Considering the weather, the attendance was fair.

A communication from Dr. Chesley on pneumonia typing and serum distribution was read, as was the monthly letter from the Executive Secretary of the State Association.

Two new members, one by card from St. Louis County, Stella L. Wilkinson, M.D., and one by application in the regular way, Carnot H. Sherman, M.D., of Bayport, were certified to by the Board of Censors and the vote for their membership was unanimous. Bernard Street, M.D., was transferred as of January to the State's Institution at St. Cloud, where he will be in charge. With him and his bride go the good wishes of the Society.

William von der Weyer, M.D., of Saint Paul gave a liberally illustrated lecture on "Hip Fractures." He pointed out physiologic reasons for the prevalence of such fractures at certain ages and described the different treatments, surgical and non-surgical, now in vogue. The very marked improvement in the treatment of such fractures has greatly increased satisfactory results, both as to life and restoration of normal or nearly normal functions. He showed and explained the instruments used by himself when surgical treatment is required.

WEST CENTRAL SOCIETY

The West Central Medical Society met in Morris, October 13, 1939. Dr. B. J. Branton of Willmar gave a short talk on malpractice. The society gave him a vote of thanks for his work. Dr. H. E. Richardson of Saint Paul gave a very interesting talk on "Diagnosis of Heart Diseases," and Dr. R. N. Barr from the State Board of Health talked on "Pneumonia: New Methods of Treatment."

Drs. I. L. Oliver, F. W. Behmler and E. M. Elsey were appointed on the fracture committee. Dr. Glesen and Dr. Robert Merrill were appointed to take a course at the University in the "Problems of Premature In-

WOMEN'S AUXILIARY

fants. Drs. L. P. Mooney and F. W. Engdahl were appointed alternatives.

According to a New Year's letter sent to members of this society by the secretary, Dr. Herman Linde, four meetings with an average attendance of fifteen were held during 1939. The present membership is thirty.

Of the original fourteen charter members, when the society obtained its charter on October 21, 1902, six are still active—Drs. Bolsta, Caine, Christensen, Elsey, Larson and Oliver. Four new members joined during the year, and one member was lost through death.—Dr. J. F. Cummings of Morris.

WOMEN'S AUXILIARY

MRS. A. C. BAKER, Fergus Falls, *President*
MRS. E. V. GOLTZ, 2259 Summit Avenue,
Saint Paul, *Publicity Chairman*

More than 10,000 papers on the subject, "Youth's Health Security," were written by Minnesota High School students in the Christmas Seal High School Radio project which is conducted under the auspices of the Minnesota Public Health Association and the Women's Auxiliary of the Minnesota State Medical Association.

A total of 102 talks selected as best from the 10,000 were submitted in the state contest. All of these had been presented by the author before local groups.

Writers of the six papers selected as best from the 102 entries presented their talk over WCCO in the final competition. They were Gloria Reel of the Cathedral High School, Saint Cloud; Barbara Zeches of the St. Charles High School, Saint Charles; Alice Hagen of the Washington High School, Brainerd; Ruth Schmiede of the Grand Rapids High School, Grand Rapids; Carl Baumgaertner of St. Thomas Military Academy, Saint Paul; and Corinne Erling of the Aitkin Junior High School, Aitkin.

Finalists who won the school trophies were in the junior contest—Corinne Erling; in the senior contest—Carl Baumgaertner.

Each of the six students who broadcast was presented with a gold medal, a gift of the Women's Auxiliary.

Representing the Auxiliary on the programs given in connection with the project were Mrs. Martin Nordland, Minneapolis, who for many years has been one of the judges in the contest, and Mrs. J. J. Ryan, Saint Paul, vice president, who appeared in place of Mrs. A. C. Baker, Fergus Falls, president, who was unable to attend.

Reports indicate that in some schools every student did research work and wrote a paper on tuberculosis as a part of this project.

Blue Earth County

The Blue Earth Auxiliary held its fall meeting at the home of the president, Mrs. W. C. Stillwell, Mankato. Mrs. George Earl of Saint Paul was a guest. After the regular business meeting Mrs. R. N. Andrews reviewed the play "The American Way." This was fol-

lowed by a social hour with the doctors. About forty members attended.

* * *

Clay-Becker Counties

Members of the Clay-Becker Medical Auxiliary held their winter meeting December 15, 1939, and elected the following officers: President, Mrs. O. O. Larson, Detroit; vice president, Mrs. H. G. Rice, Moorhead; secretary-treasurer, Mrs. L. Plancher, Detroit.

This Auxiliary has been active in sponsoring a sale of articles made by the patients at Sand Beach Sanatorium which netted \$75.85 for the patients. The proceeds are used by the patients for their Christmas spending. The Auxiliary has also placed *Hygeia* in all the county public libraries.

* * *

Red River Valley

Mrs. A. C. Baker, President of the Women's Auxiliary of the Minnesota State Medical Association, attended the joint meeting of the Red River Valley Medical Society and the Women's Auxiliary, which was held in Crookston, Minnesota, December 14, at the Crookston Hotel. Dr. W. L. Burnap of Fergus Falls talked on "The Wagner Bill" at the dinner meeting and Mrs. Baker brought greetings from the State Auxiliary.

Following the meeting, members of the Auxiliary adjourned to the home of Mrs. W. G. Paradis, where Dr. Burnap continued his discussion of the Wagner Bill, and Mrs. C. L. Oppegard reported on the Christmas Seal essay contest. The committee on *Hygeia* is composed of Mrs. S. H. Stuurmans of Erskine, Mrs. W. G. Tanglin of Mahanomen, Mrs. H. Hedemark of Thief River Falls, Mrs. Blegen and Mrs. Allen Sather of Fosston, Mrs. C. G. Uhley and Mrs. J. F. Norman of Crookston. A very interesting report was given showing an increase in subscriptions. A nominating committee was appointed by Mrs. Stuurmans, president, and includes Mrs. L. L. Brown, Mrs. O. L. Bertelson and Mrs. Uhley, all of Crookston.

* * *

Stearns-Benton Counties

Stearns-Benton Auxiliary announces the appointment of Mrs. R. N. Jones, St. Cloud, Minnesota, as their new Publicity and Press Chairman.

* * *

Washington County

The Washington County Medical Auxiliary held the November meeting at the home of Mrs. D. Kalinoff in Stillwater. The business session was followed by an afternoon of sewing for Lake View Memorial Hospital.

The annual Christmas party and meeting were held December 12 at the home of Mrs. R. G. Johnson, Stillwater. Each of the twelve members came dressed to represent a song. After a brief business meeting the afternoon was devoted to games and a visit from Santa. Luncheon followed the meeting.

The January meeting was held at the home of Mrs. E. V. Strand, Bayport, Tuesday evening, January 9, at 7 o'clock. A short business meeting was followed by dinner and the remainder of the evening was spent in a social time. Eleven members attended.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of November 8, 1939

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, November 8, 1939. Dinner was served at 7 o'clock and the meeting was called to order at 8:15 by the president, Dr. Carl B. Drake.

There were sixty-one members and one guest present.

The Secretary read a letter from Dr. Walter R. Ramsey, of St. Paul, making application for transfer of his name from the Active to the Senior Membership list. This had been approved by the Executive Committee. Voted upon and accepted by the Academy.

The scientific program followed.

TOTAL EMBOLISM OF THE RENAL ARTERY and PRIMARY CARCINOMA OF THE URETER

F. E. B. FOLEY, M.D.

Saint Paul

Dr. Foley, of Saint Paul, gave the following follow-up reports on two previously reported cases.

1. This case was originally reported at the April, 1938, meeting of the Academy. The previous report may be summarized as follows. The patient was a very obese woman age 55. She had mitral disease and auricular fibrillation. She was admitted to the hospital January 8, 1938, soon after sudden onset of severe left flank pain. There were transient hematuria, exquisite tenderness in the left flank and albuminuria. The following observations were made two days later: enlargement of the left kidney shadow in the radiograph, normal function, and outlining of the right kidney by excretion urography but no outlining whatever of the left renal pelvis and no function of the left kidney. Cystoscopy showed normal excretion of indigo-carmin by the right kidney but no efflux of urine whatever from the left ureter. By aspiration, 2 or 3 c.c. of urine not colored with indigo-carmin were obtained from the left kidney pelvis by ureteral catheter but there was no continuing drip of urine from the catheter and it appeared quite certain the left kidney was secreting no urine. The left retrograde pyelogram showed a general magnification of the pelvis and calyces corresponding to the enlarged renal outline but no obstruction or actual dilatation of the pelvis. The history and findings appeared to warrant a positive diagnosis of total embolism of the left renal artery. The pain gradually subsided and the further course was uneventful. On March 7, 1938, two months following onset, and April 5, 1938, three months following onset, most of the above observations were repeated and on both occasions a normally functioning right kidney and totally non-functioning left kidney were demonstrated. The retrograde left pyelograms made on these two subsequent occasions showed a marked de-

crease in the size of the left renal pelvis corresponding well with the shrinkage to be expected with progress of an autonephrectomy.

Since the original report the patient has continued under observation. The course has been entirely uneventful. Excretion urography and cystoscopy have continued to demonstrate a normally functioning right kidney and total absence of function of the left kidney. Since the original report April 13, 1938, retrograde left pyelograms have been made on May 6, 1938, four months after onset and on August 2, 1939, one year and seven months after onset. These pyelograms are shown in the following lantern slides. It will be noted that shrinkage of the left pelvis has continued and that in the last pyelogram this has progressed to near disappearance of the kidney.

The case illustrates the fact that with total embolism of the renal artery resulting in aseptic total infarction, autonephrectomy will progress without incident.

2. This case was originally reported at the November, 1938, meeting of the Academy. The previous report may be summarized as follows. The patient was a woman aged sixty-nine. There had been a little vague discomfort in the right flank on occasions. In June, 1938, when she first came under observation, gross hematuria was present during one day. A number of subsequent urine examinations all showed the presence of red blood cells. On pelvic examination a small mass corresponding in position to the terminal portion of the right ureter was palpable. A right pyelo-ureterogram showed a grade 2 hydronephrosis with suggestion of obstruction at the uretero-pelvic junction, no significant dilatation of the ureter but a mottled filling defect occupying a segment 4 or 5 cm. in length in the pelvic portion of the ureter. A diagnosis was made of primary tumor of the pelvic portion of the right ureter. Nephro-ureterectomy, right, and resection of the bladder including the uretero-vesical junction (one stage) were performed on July 6, 1938, and were followed by an uneventful postoperative course. On October 12, 1938, pelvic examination disclosed a small mass in the former position of the terminal portion of the right ureter. Whether this represented induration of the repair process or recurrence of the neoplasm was not certain at that time.

Since the original report, the patient has continued under observation. The mass in the right side of the pelvis gradually became larger and it became evident it represented recurrent growth of the neoplasm. Cystoscopy showed invasion of the bladder floor on the right side. A full course of deep x-ray treatment was administered by Dr. Schons. This does not appear to have had a favorable effect, for, at the last pelvic examination, October 17, 1939, the mass in the right

side of the pelvis was definitely larger and cystoscopy showed further extension in the bladder.

The course in this case is in keeping with the unfavorable prognosis usually found in cases of primary tumor of the ureter. The operation here appeared to be just as adequate as is surgically possible. There appeared to be no extension of the growth beyond the ureter and the ureter separated from surrounding structures with no difficulty whatever. The kidney, ureter and an elliptical segment of bladder wall with the uretero-vesical junction at its center were all excised intact. In spite of this, there is recurrence and certainty of an eventually fatal outcome.

Discussion

DR. ARNOLD SCHWYZER, Saint Paul: As to the first case of total embolism of the renal artery, I would like to have a little more information. When at operation you close the artery by finger pressure, the kidney becomes very much smaller right away. Here the kidney shadow was, in the first x-ray, considerably increased. Furthermore, there was blood in the urine. The question came to me, when I saw the picture, whether that was an embolism of the renal artery or a thrombosis of the left renal vein. The blood from the left spermatic vein enters the left renal vein, which then has to go underneath the superior mesenteric vessels and over the aorta to the vena cava. The venous flow is, therefore, not as free as on the right side. With the vein thrombosed, one could better understand why there was such a very great increase in the size of the kidney.

As to the second case, I wonder whether a second operation and resection would not be possible as long as the histologic picture is not very bad. A good clean excision ought to be possible and it would not be so very difficult.

DR. S. MARX WHITE, Minneapolis: Since I may lay claim to being a reformed pathologist, I might attempt an explanation supporting Dr. Foley's thesis, i.e., that, as the result of total infarction of the kidney, there is first swelling and enlargement of that organ and later contraction with diminution in size. I have had the opportunity to observe at autopsy many instances where large and smaller infarcts have occurred in the kidney. Soon after infarction has occurred the area involved is increased in size and sometimes considerably so. As time goes on this swelling diminishes and the end-result may be a scar of considerable size with pronounced shrinkage in the total mass. The same relations of early swelling and later atrophy can be observed from time to time in the brain. After death of an area in such an organ the cells and tissues imbibe fluids, the mass becomes enlarged, but these fluids are eventually abstracted in the process of organization and scar formation.

I do not recall having seen at autopsy a case of total infarction of the kidney but would expect, when this occurs, that the surrounding tissues such as the renal capsule, the circulation of which might not be involved, would furnish fluids so that swelling of the whole organ should occur similar to that seen in partial infarction. The fact that the kidney was enlarged soon after the original insult would not necessarily speak against the theory that there was infarction. In my mind, it would speak in its favor, particularly since as time goes on a demonstrated shrinkage in this organ has occurred. In my opinion the kidney shown has gone through the typical and expected evolutions.

DR. FOLEY (in closing): I should reply to Dr. Schwyzer's question concerning the diagnosis in the

case of total embolism of the renal artery. The swelling of the kidney does make one consider the possibility of venous thrombosis rather than embolic occlusion of the artery. Dr. White's comments bear directly on the question. It may be that, at the onset, the arterial occlusion is not complete and that at first only branches of the artery are obstructed with multiple infarcts with swelling at their peripheries. On the other hand, with complete arterial occlusion and perhaps ischemic damage to the venules, venous pressure may be sufficient to cause the swelling. One would not expect that venous thrombosis would progress rapidly enough to give such sudden onset of severe pain. Moreover, the proved autopsy cases in the literature correspond perfectly to the one here reported. All things considered, I can't feel there should be much misgiving about the diagnosis of embolism.

In the case of primary tumor of the ureter, I felt that the first operation was just as clean and adequate as possible and now with a recurrent, probably infiltrating, growth, I cannot feel that another surgical procedure in my hands would give any promise of success.

GENITAL TUBERCULOSIS

GILBERT J. THOMAS, M.D.

Minneapolis

Dr. Gilbert J. Thomas, Minneapolis, read his Inaugural Thesis on the above subject. (To be published in full in MINNESOTA MEDICINE.)

Abstract

1. Tuberculosis of the genital tract is a local manifestation of a general disease, and lesions here are most often secondary to a primary urinary tract infection in the kidney. The treatment plan of the local genital lesion or lesions must be based on this pathological fact.

2. The route of spread from the kidney to the genital tract is most often via the urine.

3. The primary lesion in the genital tract is most often the prostate gland. From here the infection may spread to the other genital organs. Foci of tuberculosis in the prostate gland may produce no symptoms.

4. The seminal vesicle is infrequently infected with the bacilli of tuberculosis and is most always associated with lesions of tuberculosis in the prostate gland.

5. Tuberculous infection in the epididymis is secondary in the genital tract to tuberculosis in the prostate gland. There may be a subacute stage of tuberculosis of the epididymis which is activated by trauma.

6. Treatment of lesions of tuberculosis in the genital tract consists of:

(a) The location and arrest of other lesions of tuberculosis and of the primary focus in the urinary tract by whatever means are necessary.

(b) Hygienic treatment of lesions of tuberculosis in the epididymis and heliotherapy to be followed by application of heat, incision and drainage, and surgical removal when indicated.

(c) Orchidectomy is rarely necessary.

(d) Hygienic treatment for tuberculosis of the prostate gland and seminal vesical after removal or arrest of other active foci in the urogenital tract is always

practiced. Surgical removal of these organs is seldom necessary.

(c) Postoperative rest for three months is always essential.

Discussion

DR. W. F. BRAASCH, Rochester: Dr. Thomas has taken full advantage of his opportunities at Glen Lake Sanatorium to study the cases of tuberculosis of the genito-urinary tract. He has made many interesting and valuable observations over a period of years. In the first place, he has called attention to the frequent occurrence of genito-urinary tuberculosis in cases of pulmonary tuberculosis. I was very much interested the other evening, in talking with Dr. Adamson, Director of the Manitoba Hospitals for Tuberculosis, who told me there had been quite a change in the attitude of physicians in this field toward genito-urinary tuberculosis. Careful examination, including guinea pig inoculations and urographic studies, for evidence of coincident genito-urinary tuberculosis is now usually made in cases with pulmonary tuberculosis and it is surprising how often it is found.

Whether tuberculosis in the genitalia is always secondary to renal tuberculosis, as Dr. Thomas states, or whether it may occur independently, has not been definitely proved. It is my opinion that in most instances tuberculosis in the genitalia has its origin by a retrograde route from infection in the urinary tract. Although the area of renal infection may be very slight and may heal spontaneously in some cases, yet a few tubercle bacilli may suffice to find their way from the urethra so as to infect the prostate gland and other genitalia. On the other hand, autopsy has disclosed the absence of renal tuberculosis in the presence of involvement of the prostate and epididymis. It would seem probable that tuberculosis in the genitalia may in some cases be of hematogenous origin.

Dr. Thomas has shown the great value of rest in bed with renal tuberculosis, as in other forms of tuberculosis. There are those who may not agree with him as to the length of time of rest necessary for either pre- or postoperative treatment, but its value must be recognized.

Tuberculosis of the genitalia may be very difficult to diagnose. Clinical statistics as to the incidence of involvement are not very accurate, since a slight tuberculous involvement may exist with little if any clinical evidence. In the course of the usual autopsy it may be easy for the pathologist to overlook tuberculosis of the genitalia. Without careful pathologic examination, including serial sections of all of the genital organs, the data cannot be very accurate. Exact data covering a large series of cases with complete post-mortem examination are still lacking.

Dr. Thomas is very conservative in his views regarding the treatment of genital tuberculosis and I am inclined to agree with him. On the other hand, Dr. H. H. Young believes that the tuberculous prostate gland, seminal vesicles, vas and epididymis should all be removed en masse, and he is supported in this view by men like Hinman. They claim that the postoperative results are distinctly better. The burden of the proof in a large series of cases is up to them. I formerly was under the impression that there was not much difference in the late results after nephrectomy for renal tuberculosis whether the genitalia were involved or not. However, in recent studies my colleague, Dr. Emmett, found that the late mortality in cases of renal tuberculosis was much higher in the male with clinical evidence of genital involvement than in the female. Whether this difference is entirely due to the infected genitalia is, of course, not proven. It is possible that radical surgical treatment might be considered in some cases. However, the danger of rectovesical fistulae and

incontinence, which have been observed, should make one hesitate.

Dr. Thomas is to be congratulated on his thorough discussion of this interesting subject and for his many valuable observations.

DR. F. E. B. FOLEY, Saint Paul: I too wish to compliment Dr. Thomas on the excellent work he has done the past several years in the field of genito-urinary tuberculosis. He has pursued the subject continuously and well, and in this country has been one of the outstanding contributors of clinical data on the subject. The best lesson we can learn from Dr. Thomas' presentation is that every case of genital tuberculosis, particularly epididymal tuberculosis, warrants a complete urologic investigation; for, in the vast majority of such cases, the genital lesion is secondary to a tuberculous renal lesion. To have had that fact, if nothing else, properly impressed tonight, makes Dr. Thomas' thesis well worth while.

DR. RICHARD HULLSIEK, Saint Paul (by invitation): One point that Dr. Thomas called to our attention is the high incidence of prostatic tuberculosis. I think most urologists readily recognize renal tuberculosis and involvement of the epididymis, but we have not looked often for the prostatic tuberculosis. Fortunately, the prostatic involvement often needs only hygienic treatment with the removal of tuberculosis elsewhere in the tract.

DR. F. R. WRIGHT, Minneapolis: To me this entire question is very interesting and comes down to the question of the curability of tuberculosis in general. Wherever you can get at tuberculosis and remove it, well and good; but when it comes to tuberculosis of the prostate, where one can't remove it, what are you going to do? Can you do anything but put that man out in the sun for ten or twelve years and then is he well? The probability is that sometime in the future we will develop a scheme whereby we can take care of constitutional tuberculosis, but, at the present time, that is a long way in the future.

DR. THOMAS (in closing): First of all, I want to thank the men for their discussions.

Dr. Braasch brought up the question of surgical versus hygienic treatment for tuberculosis of the epididymis. I think both methods of treatment are correct. If the patient has lesions of tuberculosis that have been controlled, indicating that his resistance is good, then I think we are justified in removing surgically an organ or tissues if such surgery will erase all remaining evidence of activity. In deciding treatment, we must not forget that tuberculosis is not alone an epididymal or prostatic infection, or a local condition. These lesions are merely local manifestations of a general disease.

Dr. Wright asks whether a patient who has had tuberculosis is ever completely cured. It is a problem with much debate whether a patient having had spread of tuberculosis from the chest cavity is ever absolutely cured. When discussing genital tuberculosis we never use the term "cured" but supplement "controlled" instead. Many patients with bilateral renal tuberculous lesions have had these under control for a great many years without symptoms. We have not found it necessary to remove surgically the seminal vesicles or prostate because, as mentioned above, when this formidable operation is performed, we are not sure that we have surgically removed all of the tuberculosis that the patient may have.

I would like to emphasize another observation, and that is that the manifestations of spread of tuberculosis from the chest cavity responding to surgical treatment are becoming fewer and fewer each year. One urologist in a large eastern city recently told me that

he now infrequently sees renal or genital tuberculosis in his wards. I visited in a city in Texas last fall with a well-known university having a medical department and large hospital. While there, I was unable to present any patients suffering with urogenital tuberculosis for demonstration purposes during my lecture. A final statement concerning treatment is necessary.

No matter where the lesion or lesions are located, if proper treatment of the disease tuberculosis is to be carried out, this must include treatment of the patient "as a whole."

The meeting adjourned.

A. G. SCHULZE, M.D., Secretary.

Meeting of December 13, 1939

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, December 13, 1939. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 p. m. by the president, Dr. Carl B. Drake.

There were fifty-four members and one guest present.

The Secretary read a letter from Dr. Franklin R. Wright, of Minneapolis, asking that his name be transferred from the Active to the Senior Membership list. This had already been approved by the Executive Committee, and, upon vote, was accepted.

The following men were elected as officers for the year 1940:

President.....James A. Johnson, Minneapolis
Vice President...John M. Armstrong, Saint Paul
Secretary-Treasurer...A. G. Schulze (relected)

The scientific program followed.

Dr. J. A. Lepak read the following inaugural thesis:

HYPOTENSION, LIKE ANEMIA, DEMANDS AN ETIOLOGIC SEARCH FOR APPROPRIATE THERAPY

An Analysis of 627 Cases

J. A. LEPAK, M.D.

Saint Paul

Although hypotension is not a disease, it is frequently associated with manifestations of a diseased or disordered constitution. Then again, in other instances, its presence reveals no evidence of ill health or loss of body vigor. Consequently, such observations must point to the existence of various types of hypotension. In this presentation, therefore, an effort will be made to give the well-known types of hypotension and to discuss especially the etiologic relation to the coexisting disease or disorder in order that rational therapy might be instituted to correct the disturbing factors. Friedlander¹ states that "there is no single explanation which can account for all types of hypotension. It is not always pathological, and where it is a manifestation of a disease, it may depend upon one of several underlying causes, or upon a combination of them."

In the definition of hypotension differences of opinion are numerous. Oliver² maintains that blood pressure below 125 mm. of mercury should be classed as hypotension, while Janeway³ lowers the reading to 100 mm. of mercury. Alvarez's studies⁴ of blood pressure in a group of 6,000 men and 8,934 women reveal an

average systolic pressure of eleven points lower in women than in men. He also noted a slight drop in blood pressure between the ages of seventeen and twenty-one in men, and seventeen and twenty-five in women. Cadbury⁵ and Kilbourn,⁶ independently, studying blood pressures in Chinese young men, found that the systolic pressure averaged from 20 to 30 mm. of mercury lower than in young Americans or Europeans. It is, then, probably conservative to classify any case as hypotension in which the systolic blood pressure reads not more than 100 mm. of mercury.

Just what the characteristic symptoms associated with or resultant from hypotension are, perhaps no one can definitely state. A certain group of symptoms may be found in one case while in another appears a totally different group. Some individuals remain symptomless, others present only a few symptoms, yet a large number show a long series of complaints. Among the most common symptoms enumerated by Roberts²¹ and Taylor²⁴ which are associated with hypotension are: loss of former sense of well-being, fatigue, physical exhaustion, motor instability, fears, apprehension, nervousness, insomnia, inability to concentrate, inattention, headache, ringing in the ears, generalized neuralgic pains, abdominal pains, falling asleep of the limbs, precordial pain, angina, dizziness, palpitation, faintness and syncope aggravated by exertion, overeating or emotion, susceptibility to colds, cyanosis of the extremities, gaseous distention, psychoneurosis, and menstrual disturbances and irregularities. To some extent, at least, the symptoms are determined by the suddenness or gradualness in the onset of hypotension. Just what mechanical, chemical or functional processes are involved in the production of hypotension with its train of symptoms is not yet fully known.

Yet despite this incompleteness in medical knowledge certain types of hypotension are clinically fairly well recognized. Thus, an acute hypotension sometimes accompanies an anaphylactic, surgical, or traumatic shock or follows a prolonged deep anesthesia. Severe hemorrhages in wasting diseases frequently produce also an acute hypotension. Less formidable hypotension appears in the acute infectious diseases, such as influenza, typhoid fever, or pneumonia. A failing myocardium, either primary or secondary in origin, accounts for many cases of hypotension. Some patients suffering from certain endocrine disturbances show marked hypotension. Essential hypotension attributed by some to the so-called "constitutionally inadequate individual" is

not very rare. Finally, a very small group is limited to orthostatic hypotension with syncope.

Most authors presume that hypotension results from a disturbance in the factors that maintain normal blood pressure. These factors enumerated by Friedlander²¹ are:

- "1. The force of the cardiac contraction.
- "2. The condition of the blood vessels.
- "3. The peripheral resistance to the blood stream, determined by the vasomotor system.
- "4. The blood volume, and the physical state of the blood itself, its viscosity, et cetera."

Inefficiency of the myocardium caused by severe infection, valvular disease, trauma, toxin, or any other such debilitating agent may produce hypotension. The contraction of the blood vessels may compensate to a certain point for the loss of the myocardial force, and for a loss of blood volume. But when the muscle fibers in the wall of the blood vessels are also injured, the muscle becoming flaccid only contributes to a further lowering of the blood pressure. Perhaps the greatest factor in the maintenance of blood pressure is peripheral resistance. It is equally important in the production of hypotension. Arterioles and capillaries, by means of the vasomotor center working in conjunction with the endocrine system, are held in a state of tonic contractions as the vasomotor impulses travel to and fro from the blood vessels. Any agent, thus disturbing the function of the muscles of the blood vessels, the nervous system innervating them, or the endocrine glands stimulating or inhibiting the vasomotor nervous system, may alter the state of the blood pressure. The last factor dealing with the change in the blood volume is particularly important in the production of some forms of acute hypotension. Although contraction of the blood vessels may compensate to a certain point for the loss in blood volume, it cannot meet the situation quickly and completely enough in severe trauma, hemorrhage, or shock to prevent dangerous hypotension. To administer appropriate treatment it is necessary, therefore, to examine as far as possible, in the light of our present knowledge, the various agents, toxic, physical, chemical, functional, et cetera, which either alone or in conjunction with others induce favorable conditions for the production of hypotension.

Temporary or acute hypotension simulates fainting. It follows most frequently an anaphylactic, traumatic or surgical shock. Sometimes a profuse hemorrhage with or without shock plays a very important rôle.

Heidenhain,²² quoted by Friedlander, injecting peptone into the blood stream, produced persistent hypotension with marked concentration of the blood. Pearce and Eisenbrey,²⁰ having confirmed the findings with peptone injections, concluded, from their experimental work on dogs, that anaphylactic shock resembled in many ways surgical shock and that anaphylactic shock and peptone intoxication in their reactions appeared identical. With the introduction of venous therapy, physicians have observed similar phenomena, sometimes following a most innocuous venous injection, which

doubtless must have contained a foreign protein. Anaphylactic shock is said to follow a partial or complete vasomotor paralysis, caused by splanchnic congestion and a subsequent disturbance of the blood volume.

Shock due to trauma received the most studious examination during the late World War by highly trained observers of France, England and America. Their studies showed first that neither injury to the heart muscle nor an exhaustion of the vasomotor center was the primary cause of the low blood pressure. Next, they demonstrated by clinical observations and laboratory experiments that a toxic factor increased permeability of the capillary walls and a consequent reduction of blood volume by the escape of plasma into the tissues. Cannon⁷ adds that after sufficient time has elapsed infection may occur and thus produce persistent low blood pressure, and explains further that there is "no essential difference between the effects of toxins given off by damaged tissue and of toxins resulting from the activity of the bacteria." Experiments of Dale and Laidlaw⁸ and Dale and Richards⁹ with the injection of minute amounts of histamin into animals produced phenomena greatly resembling hypotension in traumatic shock. They concluded that the action of histamin may be reasonably regarded as typifying the action of a large class of protein derivatives—products of partial digestion, of bacterial action and of tissue extraction. Clinical observations on the one hand show that secondary shock does not appear immediately after trauma, and comes also too early for the appearance of a well established infection, hence it can be neither nervous nor bacterial in origin. On the other hand it has been observed most frequently with extensive laceration of the muscles. Moreover, measures favoring absorption, as poor drainage from deeply seated muscle wounds, increase shock, while a check of absorption as by a tourniquet above the wound decreases shock. In addition to the histamin or histamin-like toxic agents, hemorrhage, cold, exposure, and anesthesia may aid also in the production of marked hypotension.

Surgical shock may likewise be divided into primary and secondary shock. Occasionally, a patient possessed with great fear succumbs to primary surgical shock but usually death follows secondary shock. Factors favoring surgical shock are hemorrhage, toxic agents from infection, loss of body fluids from various causes, chilling of the body, tissue trauma, rough handling of the abdominal viscera, and the anesthetic itself. There may be an interplay of several causative factors, but generally it is held that in surgical shock the arterioles are contracted tightly, that the heart contracts strongly and is ordinarily capable of raising blood pressure to a normal level and that the real cause of the low blood pressure is due to the decreased volume of blood in circulation. Accordingly, some observers classify shock as mild, moderate or severe, by the determination of the plasma volume which has left the blood vessels for the tissues. It is apparent, then, that hypotension caused by trauma and surgery with or without anesthesia has one common factor, namely, the loss of blood circulating volume, hence the treatment must be

directed primarily to the supplementing of this shortage of blood volume.

Every effort and measure, of course, ought to be instituted to prevent shock. Primary shock of nervous origin, although infrequent, should be treated without delay by rest, quiet, and nerve sedatives. Blood pressure should not be permitted to drop to a critical level by preventable delay or unnecessary procrastination. Secondary shock, however, demands swift and effective administration of concentrated solutions of glucose, sodium chloride, or gum acacia intravenously if death is to be avoided. Where hemorrhage persists, no measure should be left untried to stop it. Repeated blood transfusions, where concentrated saline and glucose solutions have failed, may save some lives. Application of heat, inhalation of oxygen, and cautious administration of drugs are also considered valuable therapeutic adjuncts.

The second large group of low blood pressure cases is found in the acute infectious diseases. Pyrexia and toxemia, playing the most important part in the production of hypotension, weaken the heart muscle, reduce the tone of the muscles in the blood vessels, and cause disturbances in the peripheral as well as central nervous system. To a certain degree the affections of the heart, blood vessels and nervous systems depend also on the type of infection and the condition of the patient prior to the infection. Some of the most frequent infectious diseases causing hypotension are: typhoid fever, pneumonia, influenza, diphtheria, scarlet fever, cholera, malaria, epidemic cerebrospinal meningitis, typhus fever, and trichinosis. In the advanced stages certain chronic diseases, like tuberculosis, syphilis, diabetes, bronchial asthma, and food deficiency may be likewise very disturbing. Sometimes long-standing focal infections, anemia, cachexia, or a debilitating disorder may cause hypotension.

The treatment of hypotension associated with or following on the heels of an infectious disease, consists largely in ridding the patient of the disease. Wherever possible, specific drugs or sera should be employed. In most cases supportive and symptomatic treatment usually suffices, and after the disease has been terminated for some time hypotension disappears. Some cases, however, retain hypotension either for a long time or permanently and may or may not require a restriction of their activities.

The third group of hypotension results from cardiac weakness or failure. This may come on rather gradually like in valvular disease or suddenly as in coronary thrombosis. Valvular disease as a long-standing mitral stenosis or severe hypertension may, in time, wear down the myocardium and produce secondary hypotension. A large aortic aneurysm without aortic insufficiency not infrequently produces hypotension. Some of the long and frequently recurring paroxysmal tachycardias and bradycardias associated with Stokes-Adams syndrome show either temporary or permanent hypotension. Obesity and long-standing focal infections and toxic states like diabetic coma often produce myocardial weakness with secondary hypotension.

Since hypotension in this group, like in the preceding

two, is relative and is produced entirely by weakness or inadequacy of the propelling force, the treatment must be directed primarily to the strengthening of the myocardium. Rest, digitalis, mild physiotherapy, massage, sun baths, sedatives, and an appropriate diet for individual needs constitute the most commonly employed therapeutic procedures for myocardial weakness. Coronary thrombosis and toxic or infectious myocarditis, each call for its specific line of treatment.

The fourth group causing hypotension is vague and indefinite. It depends on the disorders or disturbances of some of the endocrine glands, among which the best known conditions are Addison's disease, hypopituitarism and hypothyroidism. The hypoadrenalemia, hypoglycemia, and lowered basal metabolism of Addison's disease sometimes cause not only hypotension but also all the symptoms of a mild shock. Friedlander¹¹ calls attention to certain constitutional diatheses commonly associated with cardiovascular, nervous, muscular and glandular hypoplasia or dysfunction. He mentions particularly status lymphaticus, infantilism, myasthenia gravis, and adiposis dolorosa. Body habitus, exposure to high temperature and variations in atmospheric pressure have also a tendency to produce hypotension.

In this group of hypotension the treatment will vary as the agent varies which produces a certain disease, a functional disturbance, or an anatomic abnormality. While Addison's disease may be treated principally with cortin, and hypothyroidism with thyroid extract, some of the less understood conditions naturally will receive treatment which primarily improves health and retards disease and secondarily acts favorably on hypotension.

The fifth, not large but very interesting, group comprises postural or orthostatic hypotension, which results from the abnormal gravitation of blood when the subject is in the erect position. Normally, a change of the body from the supine to the erect position throws an extra strain on the circulation and the organism physiologically adjusts itself by increasing the pulse rate and raising the diastolic while lowering the systolic blood pressure. But in 1925, Eggleston and Bradbury¹² discovered three cases of hypotension which failed to conform to this physiological concept. They suffered from syncopal attacks after or during exertion and sometimes even after standing erect for some minutes. The pulse remained slow and the rate unchanged, the basal metabolism was lowered, perspiration was lacking, and the patients were worse during the summer. The first case in this series is quoted because it shows the unusual blood pressure readings and the accompanying clinical findings quite characteristic of the whole group.

The patient was a male, thirty-eight years old, suffering from "terrible weakness," constant headaches, nocturia, and spots before the eyes. In the lying position the blood pressure read systolic 110, diastolic 65; on standing it fell to systolic 80, diastolic 40 mm. of mercury. After slight exercise there was no dyspnea nor any increase in pulse rate, but in one minute the head fell back, the pupils dilated, slight convulsive movements appeared and, with increased pallor, unconsciousness and loss of radial pulse followed. Then after five

minutes in the reclining position the blood pressure rose to 60 systolic, 40 diastolic mm. of mercury and recovery took place. Blood pressure readings taken on several occasions always showed the lowest values in the standing, slightly higher in the sitting and the highest in the lying position. Having designated these cases as postural hypotension the authors studied the effects of epinephrin, atropin, and pilocarpin, in the lying, sitting, and standing positions, and from the clinical observations and laboratory studies concluded that only a paralysis of the sympathetic vasoconstrictor endings seemed to explain adequately the blood pressure reactions in their cases.

In 1927, Bradbury and Eggleston⁵ reported that two of their patients had died, rather suddenly. The anatomical diagnosis on one of the cases at postmortem was: chronic myocarditis, acute dilatation of the heart, atrophy of the prostate gland, and chronic tuberculosis of the bronchial lymph nodes. As postural hypotension became recognized as a clinical entity, case reports appeared in various sections of the country. Bar and Duggan³ reported postural hypotension in a negro suffering with Addison's disease. Sanders^{22,23} observed it with chronic diarrhea and tachycardia. After reviewing the literature, Barker⁴ recorded a case with numerous laboratory studies. Laubry and Dourne¹⁷ introduced the term "orthostatic" hypotension. Weis²⁵ reported a cure of a case with ephedrine sulphate. Reporting a case with unusual features, Alvarez² states that most cases show:

- "1. Sharp drop in systolic and diastolic pressure with syncope when they stand.
- "2. Failure of pulse rate to increase so as to compensate for drop in pressure.
- "3. Deficient sweating and inability to stand hot weather.
- "4. Secrete large volumes of urine at night.
- "5. Additional features frequently, such as appearance of youthfulness, lowering of basal metabolism, signs of slight changes in the nervous system, loss of sexual desire, and concentration of blood urea around the upper limit of normal."

Ghrist and Brown²² contend that the splanchnic vessels lack resistance, and the vagal cardiac regulatory mechanism is deficient in failing to increase the heart rate to compensate for the alterations in blood pressure. Others following the hypothesis of MacWilliam¹⁸ assign the disturbing agent to the lower extremities. Doubtless the vasomotor system plays the principal part in the production of postural hypotension, but as long as the physiological processes remain unknown or only partially worked out, theories regarding the cause will be constantly increasing.

In treating orthostatic hypotension every effort should be exerted to maintain blood pressure above the level which produces undesirable symptoms when the patient is erect. Among the drugs found most useful in the treatment of postural hypotension were ephedrine sulphate, benzedrine sulphate, ergotamine tartrate and paredrine hydrobromide. Ghrist and Browne²² reported

a cure with ephedrine sulphate. Horton and Brown,¹⁴ after experimenting with various medications, combined ephedrine sulphate with paredrine hydrobromide and thus obtained the most satisfactory results. When postural hypotension is better understood, unquestionably the treatment will be also more efficacious.

The sixth group embraces essential hypotension, a syndrome whose chief objective finding is marked hypotension. Among the symptoms listed are exhaustion, nervousness, headaches, pains in the chest, abdomen or extremities, indigestion, constipation, backache, dyspnea, insomnia and palpitation. Not infrequently such patients are diagnosed as neurasthenics, psychasthenics or psychoneurotics. They are individuals usually between the ages of twenty and forty and the condition is at least twice as common in women as in men. There is a lack of the usual stamina necessary to meet the daily routine of life. Among the theories advanced to explain essential hypotension are an asthenic type of individual, status lymphaticus, autointoxication, decreased oxidation, constitutional inferiority, preceded possibly with endocrine disturbances or post-infectious exhaustions or toxemias, storage of excessive quantities of blood in the splanchnic vessels, and capillary stasis due to histamin or histamin-like bodies. Although medical writers disagree on the theory of causation, they all agree that the individuals lack necessary endurance, mental, physical and emotional. As long as they are sheltered and, either by accident, circumstance or design, prevented from unusual strain and stress of modern civilization, their limited constitutional capacity operates smoothly and satisfactorily. When ambition stimulates them to compete with the robust type, or occupational worries, familial disturbances, domestic wrangles, or financial reverses place an additional strain on the constitution, a marked depreciation in health results.

In the treatment of essential hypotension it is necessary to recognize the subnormal physical, mental and emotional strength of the individual in order to regulate his activities, choose an occupation, select a diet, insist on rest and prescribe drugs to maintain or increase his vigor instead of employing measures which might tear down or destroy it. Such treatment is always difficult and painstaking. Essential hypotension found in the fairly robust type resulting from overwork or some acute infection, responds to treatment more readily than the former.

Comment

Hypotension in the light of our present knowledge might be regarded as a symptom of some known or unknown causes, sometimes predictable and many times unpredictable. Clinical, laboratory, and experimental evidence favor a theory of multiple and sundry causes rather than one and unique for the production of hypotension. Whether the constant accumulation of knowledge may unearth one single initiating, directing or guiding link in the long chain of causes held today, remains a moot question for the future. Any classification of hypotension in recent years is unsatisfactory because frequently cases in one group overlap with

another when they manifest similar or identical characteristics. And to complicate the picture still further, many of the symptoms and findings attributed to hypotension are observed in perfectly normal individuals or even sometimes in cases of hypertension. It is safe to say, however, that the disturbance or failure of two factors—the heart or driving force and the vasomotor controls—account for hypotension in the majority of cases. Other factors, like hemorrhage or loss of body fluids, are of relatively rare occurrence and from the numerical standpoint negligible. Endocrine dysfunction, toxemias (endogenous or exogenous) and infections with their toxins are important in the production of hypotension only in so far as they depress cardiac or vasomotor action and when compensatory functional mechanisms, such as increased pulse rate, or rising blood pressure, do not appear. In recent years, operations performed on the sympathetic nervous system, such as bilateral ramisection, ganglionectomy, bilateral vascular sympathetic neurectomy for hypertension and vascular crises, as Raynaud's disease or erythromelalgia, have given not only satisfactory results but have proven also that blood pressure is actually controlled by the sympathetic nervous system. It is apparent, then, that the most important single factor in the production of hypotension is a disturbed vasomotor control.

Conclusions

1. Hypotension is a symptom.
2. For practical purposes, especially for treatment, six groups are proposed on a more or less recognized etiological basis. These are:
 - a. Hypotension due to shock (trauma, surgery, anesthesia) causing peripheral nerve-paralysis and treated largely by introduction of concentrated solutions intravenously.
 - b. Hypotension in acute infectious diseases caused by toxins acting upon the whole organism but especially on the myocardium and treated by supportive therapy.
 - c. Hypotension resulting from myocardial insufficiency due to long-standing causes, like valvular disease or hypertension, and treated by supporting the myocardium.
 - d. Hypotension encountered in endocrine dysfunction or constitutional diatheses and treated by specific or pluri-glandular replacement therapy.
 - e. Hypotension (orthostatic) discovered only recently and resulting from abnormal gravitation of blood when the subject is in the erect position and treated best by large doses of ephedrin sulphate and paredrine hydrobromide.
 - f. Hypotension (essential) found in relatively well individuals, frequently without any complaints due to constitutional deficiencies and either not treated or treated only symptomatically.
3. An analysis of 627 cases of hypotension in the first examination at the office in regard to presenting complaints, family history, age, sex, tuberculosis, social

state, operations, past history, infectious diseases, occupation and final diagnosis indicates that modern stress and strain in undermining the vegetative nervous system plays a major part in the production of hypotension.

Discussion

DR. ALBERT SNELL, Rochester: Dr. Lepak has mentioned the importance of blood volume in the maintenance of normal arterial tension. This fact is well exemplified by the course of patients who have Addison's disease. During periods of crisis, the blood pressure falls to extremely low levels, chiefly owing to hemoco-concentration and a decrease in blood volume. Administration of the synthetic cortical hormone, desoxycorticosterone acetate, produces retention of salt and water and, if used in a dosage larger than necessary, there may be a sufficient increase in blood volume to produce actual hypertension. In fact, cardiac dilatation and acute cardiac failure may be induced by this means in cases in which Addison's disease is present. The relation of blood volume to blood pressure has not been extensively studied in all types of hypotension, but, certainly, the importance of normal blood volume in this group of patients may well be greater than was formerly believed.

LYMPHOSARCOMA OF THE STOMACH AND BOWEL*

Report of Two Cases

JAMES A. JOHNSON, M.D.

Minneapolis

Lymphosarcoma of the gastrointestinal tract is a relatively uncommon disease. In 1932, Ullman and Abeshouse⁶ reported that there were 375 cases of the small and large intestine. In March, 1939, Madding⁴ reported that there were 428 cases up to 1938 of all types of sarcomas of the stomach and collected sixty-seven additional cases from the Mayo Clinic, 81 per cent of them classed as lymphosarcomas. Collins¹ states that sarcomata comprise about 1 per cent of all neoplasms of the stomach. In comparison with the stomach and colon the small intestine is relatively free from malignancy. Lymphosarcoma, however, is probably found as frequently as any other form of malignancy in this locality. This is especially true in the ileum.

Statistics are undoubtedly quite unreliable because of the confusion which arises as to its terminology. Ewing² has given a most comprehensive discussion of this subject in the February, 1939, Bulletin of the New York Academy of Medicine. Any one who desires detailed information should read his article. Lymphosarcoma is often reported as sarcoma of either the large or small cell variety. It is often mentioned as intestinal Hodgkin's disease, malignant lymphocytoma or lymphoblastoma. These distinctions are probably only of academic value, at least as far as the clinician is concerned. It has, therefore, often been suggested that the general term of lymphoblastoma be used to obviate the confusion.

The etiology of lymphosarcoma is as obscure as it is in all other malignant diseases. Trauma has often been mentioned in individual reported cases, but it is usually difficult to establish any definite relationship. Ewing states that subacute bacterial infection stands as one of the common excitants of lymphatic tumors. There is perhaps some irritant present that incites cell growth, but the cause awaits further development, as is the case in all malignancy.

Lymphosarcoma of the gastrointestinal tract is most common in the first, third and fourth decades of life, the average age being about forty years. The average age in Ullman's series of intestinal cases was 33.19 years, males showing a preponderance of 5 to 2. It is most frequent in the white race. The average age of gastric cases reported by Madding was forty-six years. Males were affected in a proportion of 6 to 1.

Lymphosarcoma in the stomach and intestine appears either as an annular or polypoid growth. The annular or infiltrating type is more common. It begins in the lymphoid tissue of the submucosa and spreads laterally into the muscular layers, which it gradually replaces with a hard infiltrating growth. The growth appears as a subserous tumor which usually does not penetrate through the serosa but often invades the mucosa and causes ulceration. The tumor is of a firm

consistency and often has an irregular contour. In the stomach it may resemble diffuse carcinoma, the so-called "linitis plastica." It spreads by direct extension into the adjacent lymph nodes and later to distant organs either by lymphatic or blood channels. It occasionally perforates. Lewis³ found only six instances of perforation out of 400 reported cases.

The diagnosis is rarely made before operation. There are no classical signs or symptoms by which it can be recognized. The symptoms are usually of an obscure nature and consist of an indefinite gastric or abdominal distress, depending largely upon ulceration of the mucosa or obstruction to the lumen for their localization. A secondary anemia together with moderate leukocytosis is usually present. Roentgen examination is the greatest aid to diagnosis. The gastric rugæ are decidedly enlarged, suggesting a marked submucosal infiltration, much resembling an advanced hypertrophic gastritis. The general picture is that of a gastrointestinal malignancy and that is the usual preoperative diagnosis.

Treatment consists of surgery and x-ray therapy. It represents much the same problems as any other malignancy. Lymphosarcoma, unfortunately, does not produce as early obstruction and ulceration in the gastrointestinal tract as does carcinoma, and is, therefore, usually more advanced. It metastasizes early and widely into the surrounding glands and the result is, therefore, less favorable. If the lesion can be recognized early enough to permit a thorough removal, the eventual result will no doubt compare favorably with other malignancies.

Case Report

Case 1.—Mrs. L. B., aged fifty-six, housewife, came to the office on August 8, 1939, referred by her family physician, Dr. F. R. Huxley.

Past history: She had had typhoid fever during childhood. During the past ten years there had been recurrent attacks of abdominal pain of short duration.

Present illness: During March, 1939, she had an attack of influenza and since then had not been well. She began to notice epigastric distress after meals which had gradually increased until at the time of her examination it was very severe and she often vomited before there was any relief. Recently, the stools had been loose, often three to five stools daily. There had been a weight loss of 15 pounds the past five months.

Physical examination: Revealed considerable loss of weight with pallor. A hard mass could easily be palpated in the epigastrium. The abdomen was slightly distended. The heart and lungs were normal; blood pressure was 100 systolic, 70 diastolic.

Laboratory findings: Urine negative; hemoglobin 55 per cent; red blood cells 3,700,000; leukocytes 13,200 with 81 per cent polymorphonuclears; Kolmer and Kline negative. No gastric contents were examined because of her fear of this procedure.

X-ray examination: Revealed a large lesion of the stomach involving two-thirds of the pyloric end with 25 per cent retention at the end of six hours. The diagnosis was advanced carcinoma of the stomach, probably operable.

Operation (August 20, 1939): General anesthesia. On opening the abdomen there was found a large growth involving almost the entire stomach. The adjacent glands on the lesser and greater curvature were extensively involved. There were several enlarged glands

*From the Department of Surgery, The Nicollet Clinic, Minneapolis, Minnesota.

in the mesentery of the small bowel. The liver and remainder of the abdomen were free. I decided to remove the growth so that she could eat in comparative comfort as long as she lived. An extensive removal was done, leaving only a small pouch to which the jejunum was anastomosed by the Polya method. An entero-anastomosis between the two arms of the jejunum was then made. Five hundred cubic centimeters of blood and 1000 c.c. of 5 per cent glucose in normal saline were given intravenously during the operation.

Post-operative condition: Uneventful until the third day, when she developed a generalized edema. This was probably a salt retention edema enhanced by her anemia. There was also a circulatory factor. She was given several intravenous injections of 10 per cent glucose in distilled water together with a blood transfusion and digitalis. The edema had disappeared in four days and the remainder of her convalescence was normal.

Pathological report: Gross: There is a massive tumor involving about two-thirds of the mucosa of the resected portion of the stomach. This tumor is thrown up into enormous folds which roughly resemble normal gastric rugæ. There is ulceration at several points. The wall is about 1.5 cm. in thickness and the muscular layer is visible at the base of the tumor. The peritoneum is heavily infiltrated with large thick plaques. In the attached mesentery there are soft yellow white lymph nodes ranging up to 1.5 cm. in diameter.

Microscopic sections: Show a massive infiltration by small round cells, endothelial cells, eosinophiles and polymorphonuclears. This is present both in the gastric tumor and the lymph nodes. Because of the variation in the size and form of the cells, leukemic infiltration is improbable and by exclusion the diagnosis of lymphosarcoma or Hodgkin's is made.

The picture corresponds to the condition previously classified as lymphosarcoma.

Result: She returned to her home on September 24 with instructions to come back after a short convalescence for x-ray treatments. About three weeks later her family physician, Dr. Huxley, telephoned that she had become deeply jaundiced. She died on November 1, apparently from a rapid extension of the growth.

Comment: During the operation it was found that there was massive infiltration about the head of the pancreas and bile ducts. The tumor growth evidently progressed rapidly and caused an obstructive jaundice.

Case 2.—Mr. H. M., aged sixty-seven, a retired farmer, came to the office August 22, 1939, referred by his family physician, Dr. A. W. Sommer.

Past history: Typhoid fever at the age of twenty, appendectomy at twenty-two. Gastric distress eighteen years ago relieved by diet and medication. Otherwise general health had been good.

Present illness: During the past five months he had noticed epigastric distress with some distention. The past two months pain had localized in the left upper abdomen and was most severe directly after eating. There had been some nausea but no vomiting. He had lost twenty pounds the past five months. One week previous to my seeing him he first noticed a lump in his left upper abdomen.

Physical examination: A poorly nourished man with a hard irregular mass the size of a fist in the left upper abdomen. The mass was freely movable from side to side. The spleen could be felt separately and was not involved in the tumor. Lungs and heart were normal; blood pressure 124 systolic, 70 diastolic.

Laboratory findings: Urine and Wassermann negative; hemoglobin 59 per cent, red blood cells 4,560,000

—deformed cells; leukocytes 13,800, differential white cells normal.

X-ray examination: The stomach and colon were normal. The mass was located in the jejunum. There was partial obstruction and some barium was retained in the tumor. A diagnosis of jejunal tumor was made and operation advised.

Fig. 1. (above) Lymphosarcoma of stomach, showing diffuse infiltration of the wall together with extensive involvement of the mucosa with ulceration.

Fig. 2. (below) Specimen of jejunum with wall and lymphatic glands extensively involved.

Operation (August 25, 1939): Left upper rectus incision. A large diffuse infiltrating tumor was present in the upper jejunum. About 30 inches of the bowel and mesentery were extensively involved with an infiltrating growth. The infiltration extended to the base of the mesentery and beyond. There was no evidence of distal metastasis. The entire growth including a wide area above and below was excised. The mesentery was removed down to its junction with the posterior wall. The growth extended beyond this point behind the peritoneum and could not be completely excised. The growth was high on the jejunum and there was just room enough for a side-to-side anastomosis. He was given a 500 c.c. blood transfusion following the operation.

Post-operative: Except for a slight cold his recovery was normal. He left the hospital on the eighteenth day to return later for x-ray treatment.

Pathological report: Gross: The specimen consists of a long segment of bowel and its mesentery. The bowel wall at several points is over 1 cm. in thickness. The entire segment is infiltrated by a grey diffuse tumor which is located principally in the peritoneal and muscle layers. At numerous points the mucosa is also

involved and a few of these areas are ulcerated. The mesentery is involved by masses of grey lymph nodes which are fused together, producing shortening of the mesentery and adhesions of the bowel loops. The mesenteric mass at one point is about 4 inches in diameter.

Microscopic sections: Sections of the bowel and nodes show that they are completely destroyed by a growth of round lymphoid cells. Mixed with these are larger endothelial-like cells together with leukocytes, both polymorphonuclears and eosinophiles.

Diagnosis: Lymphoblastoma of the bowel and mesentery. The term lymphoblastoma is a general one applied to this group of diseases. The term lymphosarcoma is the one in most common usage.

Result: On October 24, 1939, he returned for deep x-ray therapy. He stated that he was feeling fairly well and had no pain or distress. He was able to take a general diet and gained a little weight. The secondary anemia showed improvement.

Comment: The growth had extended deep into the retroperitoneal glands, which could not be removed. His relief, therefore, will only be symptomatic and will depend on the rapidity or slowness of growth of the remaining tumor.

Conclusions

1. Lymphosarcoma of the stomach and bowel is a comparatively rare disease. It occurs often enough, however, so that the surgeon should be constantly on guard and not fail to recognize its presence. It is with this in mind that I have reported in detail these two cases.

2. The etiology is unknown.

3. It begins as a local disease in the lymphoid tissue of the submucosa and spreads to infiltrate all the layers.

4. The treatment is the same as that of any malignant neoplasm.

Discussion

DR. ALFRED HOFF, Saint Paul: It may be of interest to cite a case I first saw in 1932 and followed for seven years until her death in 1939. This patient, fifty-seven years old when first seen, complained of pain in the left side of her abdomen. X-ray studies after a barium enema revealed a constant filling defect in the cecum. Malignancy was considered probable and a cecal resection was done by Dr. A. R. Colvin. The tumor found in the cecum had a convolutions-of-the-brain appearance and the microscopic diagnosis was lymphosarcoma.

Three years later this patient developed a chyloid effusion and an indefinite nodular mass appeared in the abdomen. About this same time palpable discrete lymph glands were found in the groin and axilla. The spleen and liver were not palpable.

From this time until her death four years later she was rarely confined to bed, although dyspnea on moderate exertion became increasingly evident.

During all of this time repeated blood examinations, except for a moderate anemia and leukocytosis with a neutrophilia, were not significant.

No x-ray therapy was attempted.

A complete blood study made on the day preceding her death failed to show any signs of immaturity or changes indicating the leukemia which was found at autopsy.

DR. A. R. COLVIN, Saint Paul: The case reported by Dr. Hoff, in connection with Dr. Johnson's case reports, presented some points not referred to by Dr. Hoff. The patient had complained for years of abdominal pain and in the course of Dr. Hoff's examination he discovered with radiography a fairly large stone in the left kidney. Pyelogram revealed a marked dilatation of the calices with retention of the contrast medium for several days. I may say that the kidney condition was ignored for the time-being because of the presence of a palpable tumor in the cecal region; radiography revealed a filling defect in the cecum. Operation was undertaken because of the possibility of carcinoma of the cecum. At the operative exposure it was remarked that the tumor did not have the feel of what we are accustomed to find in carcinoma of the large bowel, but felt like a diffuse uniform enlargement extending well up into the ascending colon. On removal of the colon well on into the transverse, the mucous membrane was uniformly thickened and presented a wavy appearance. There was no glandular enlargement. Strange to say, she had no more pain after recovering from the operation, although the stone in the kidney was not disturbed and she had a marked hydronephrosis. The stone and hydronephrosis was found also at autopsy. Dr. Hoff has told you she lived six years. Her death was due, as Dr. Hoff has told you, to a generalized pseudo-leukemia. Preceding her operation, she had remarkably few gastrointestinal symptoms.

I suppose the question might be raised whether a condition such as was found in her colon required surgery. It is possible that she might have lived just as long without operation, but perhaps in a similar case one would again be uncertain as to the condition found at exploration in the absence of glandular enlargement, as in the case reported.

Dr. Johnson's cases are reported as lymphosarcoma. The large group of conditions including pseudo-leukemia, lymphosarcoma, Hodgkin's disease and lymphomatosis are at times very difficult of differentiation clinically and perhaps this is true histologically.

The next case was perhaps even more confusing. A woman of fifty-four complained of persistent nausea and occasional vomiting, in the presence of tachycardia, a basal metabolic rate of plus 40, and a fairly marked bilateral enlargement of her thyroid gland. Hyperthyroidism was a probability and still the clinical picture was lacking in some of the elements of hyperthyroidism. The patient did not look like a toxic goiter complex. Radiographic study of the stomach was negative.

The thyroid enlargements felt much firmer than any of the usual enlargements. Riedel's granuloma was thought of but, at operation, on incising the gland it lacked the tough fibrous condition found in Riedel's granuloma. The cut surface resembled that of a firm sarcoma. Subtotal removal was done, and, although immediate recovery was satisfactory, the patient died in about three months. At autopsy, a pseudo-leukemic infiltration of the submucosa of the entire stomach was found, the mucous membrane being thrown into coarse wavy folds very much like that seen in the colon of the other case. There was a firm nodule about the size of a large bean in the wall of the small intestine, and a similar one in the wall of the left ventricle; there was quite an amount of milky fluid in the peritoneal cavity.

Here, then, we have a generalized disease presenting local lesions confusing as to interpretation. The disease is a generalized one and always fatal. The increased basal metabolic rate is perhaps always present and should call attention to a condition in which surgery is only temporarily helpful.

DR. HERBERT JONES, Minneapolis: I would like to ask Dr. Johnson what the effect of the x-ray was on this growth?

DR. JOHNSON: It is only about six weeks since he completed the x-ray treatments and not enough time has passed to notice any changes. I believe it is quite generally recognized that x-ray treatments of this type of tumor are often followed by favorable results for a considerable period of time.

DR. J. A. LEPAK, Saint Paul: I had a case with this condition and the operation was performed by Dr. Arnold Schwyzer. He opened the abdomen, recognized the condition by its gross pathology, and simply closed it. The case then received x-ray treatment and has been perfectly well for three years.

The meeting adjourned.

The Negro and the City

Cities are relatively much more destructive to Negroes than to whites in their effects on mortality from tuberculosis and acute respiratory infections. Under present conditions mortality from respiratory diseases acts as a powerful check to the natural increase of the Negro in northern latitudes. Holmes, S. J., Amer. Jour. Med. Science, 1938, 195.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

INTRODUCTION TO GASTRO-ENTEROLOGY. Third Edition of The Mechanics of the Digestive Tract. Walter C. Alvarez, Professor of Medicine, University of Minnesota, the Mayo Foundation, and Senior Consultant in the Division of Medicine, Mayo Clinic. 778 pages. Illus. Price, \$10.00, cloth. New York: Paul B. Hoeber, 1940.

CANCER OF THE BREAST AND CANCER OF THE UTERUS. Second Edition. Marion Ellsworth Anderson, A.B., M.D. 106 pages. Illus. Price, \$3.50, cloth. Clinton, Iowa: Franklin Press, 1939.

POPULATION, RACE AND EUGENICS. Morris Siegel, M.D. 206 pages. Price, \$3.00, cloth. Hamilton, Canada: Dr. Morris Siegel, 1939.

LANE MEDICAL LECTURES: VIRUSES AND VIRUS DISEASES. Thomas M. Rivers, M.D., Sc.D., Director Hospital of the Rockefeller Institute for Medical Research, New York City. 133 pages. Illus. Price, \$2.50, cloth. Stanford University, California: Stanford University Press, 1939.

MANUAL OF FRACTURES, DISLOCATIONS AND EPIPHYSEAL SEPARATIONS. Harry C. W. S. de Brun, M.D., F.A.C.S., Adjunct Professor of Surgery, New York

SILVER PICRATE

Wyeth

Has shown a CONVINCING RECORD* OF EFFECTIVENESS in ACUTE ANTERIOR URETHRITIS

**due to *Neisseria gonorrhoeae* • *Trichomonas vaginalis*
*Monilia albicans***

Silver Picrate is a crystalline compound of silver in definite chemical combination with picric acid. Dosage form for use in anterior urethritis: Wyeth's Silver Picrate Crystals in an aqueous solution of 0.5 percent.

Supplied at all pharmacies in vials of 2 grams

Complete literature on Silver Picrate as used in genitourinary and gynecological practice will be mailed on request.

*"Treatment of Acute Anterior Urethritis with Silver Picrate," Knight and Shelanski, AMERICAN JOURNAL OF SYPHILIS, GONORRHEA AND VENEREAL DISEASES, Vol. 23, No. 2, pages 201-206, March, 1939.

HANDBOOK OF ORTHOPÆDIC SURGERY. Alfred Rives Shands, Jr., B.A., M.D. Medical Director of the Nemours Foundation, Wilmington, Del.; Associate Professor of Surgery in Charge of Orthopædic Surgery, Duke University School of Medicine, Durham, N. C. 567 pages. Illus. Price, \$4.25, cloth. St. Louis: C. V. Mosby Co., 1940.

THE PATIENT'S DILEMMA. The Quest for Medical Security in America. Hugh Cabot, M.D. 284 pages. Price, \$2.50, cloth. New York: Reynal & Hitchcock, 1940.

DON'T EAT BREAD. Allen Klein, Ph.G. 116 pages. Price, \$1.00, cloth. Emmaus, Pa.: Rodale Press, 1939.

PRIMER OF ALLERGY. Warren T. Vaughan, M.D., Richmond, Va. 140 pages. Illus. Price \$1.50. St. Louis: C. V. Mosby Co., 1939.

This book is designed, one might say, as a companion volume to the "Practice of Allergy," which we reviewed earlier. The latter is a text designed for physicians. The "Primer" is designed to explain to laymen the concepts of allergy.

There are some sections on general instructions which should prove distinctly helpful. In general, however, it is my impression that the book attempts to be too complete, with the result that the average lay reader, when he has finished the first hundred pages, will feel almost as confused as when he started. For those patients interested in as complete an understanding as possible of our present knowledge of allergy the book will prove distinctly interesting.

On the whole one might wish a volume about one-half the length and about one-half the complexity. The few illustrations give one the idea that a volume making all its points with numerous pictures might be more effective than a volume indulging in considerable verbiage.

ASHER A. WHITE, M.D.

DISEASES OF THE CORONARY ARTERIES AND CARDIAC PAIN. Robert L. Levy, M.D. 445 pages. Illus. Price, \$6.00. New York: The Macmillan Co., 1936.

Unfortunately, this book was not presented for review when first published. However, a review at this time must not be considered as unsatisfactory because of the lapse of three years. In fact, the list of contributors is sufficient assurance of the value of the work as edited by Robert Levy. Men were selected who were outstanding in their fields to write the various chapters; for example, anatomy being described by Wearn, physiology by Wiggers, pharmacology by Fred Smith, and pathology by Von Glahn. Levy, Kerr, and Wilson contribute a discussion on the clinical data of coronary disease and its complications. The medical treatment is ably handled by Levy himself. There are also appended several interesting chapters on the sur-

gical treatment of diseases of the coronary arteries, including a contribution by James C. White on paravertebral alcohol injections and other measures for the relief of cardiac pain; Beck's surgical treatment for the development of a new blood supply to the heart; and a discussion by Blumgart on his results with total thyroidectomy for the relief of cardiac pain and congestive heart failure.

F. J. HIRSCHBOECK, M.D.

EYE, EAR, NOSE, AND THROAT MANUAL FOR NURSES. Roy H. Parkinson, M.D., F.A.C.S., oculist and aurist to St. Joseph's Hospital, San Francisco, Calif. Fourth edition. 243 pages. Illus. Price, \$2.25. St. Louis: C. V. Mosby Co., 1939.

This volume gives the subject matter briefly, yet with remarkable clearness and completeness. The material is arranged skillfully and the illustrations are well selected.

D. L. TILDERQUIST, M.D.

TUMORS OF THE HANDS AND FEET. Edited by George T. Pack, B.S., M.D., F.A.C.S., Assistant Clinical Professor of Surgery, Yale University, School of Medicine and Cornell University, College of Medicine. Price \$3.00. 138 pages. St. Louis: C. V. Mosby Company.

This little volume is a reprint of a symposium on this subject which appeared in the January, 1939, issue of *Surgery*. There are a number of collaborators who assemble the present knowledge of the subject in very convenient form. The book is well illustrated and well indexed and has a complete bibliography. It should be useful both for the purpose of getting up to date information on the subject and also for reference.

GORDON C. MACRAE, M.D.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

(Continued from Page 130)

he was born in Denmark in 1863, and that he has been in this country forty years. He holds no license to practice any form of healing in the State of Minnesota, and stated that he has a diploma in mechano-therapy from the American College of Mechano-Therapy at Chicago, dated November 18, 1908. He has lived in Minneapolis for about twenty years and has represented himself to the public as a naturopathic physician. At the time of his arrest he was representing himself as a physiatric specialist in women's ailments. Prior to residing at the Humboldt Avenue address, Visholm practiced at Portland and Lake Streets and at 1700 West Lake Street. Visholm, when questioned by Judge Reed about practicing without a license, stated to the Court that the naturopaths had attempted on four occasions to have naturopathy recognized by the Minnesota Legislature, but that the bill had been defeated each time.

The Minnesota State Board of Medical Examiners approves of the disposition made of this case due to the defendant's advanced age, and because of his frankness in acknowledging his guilt at the time of his arrest, and other circumstances connected with the case. The Medical Board also wishes to acknowledge the very prompt and splendid work done in this case by the Women's Bureau of the Minneapolis Police Department, and particularly by Lieutenant Blanche Jones, head of the Bureau, and Mrs. Carrie Bystrom and Miss Gladys Cooke, policewomen.

CESAREAN SECTION*

A Brief Historical and Technical Review

L. W. BARRY, M.D.

Saint Paul, Minnesota

ACCORDING to Greek mythology, Bacchus⁵⁸ was taken from the dead body of his mother, Semele. Æsculapius was born in a similar manner. Among the Romans, Pliny⁵² mentions that Scipio Africanus and Manilus were born in this way. Numa Pompilius,² the second king of Rome, decreed that no pregnant woman should be buried until the fetus had been extracted by abdominal section. Julius Caesar⁷⁰ was supposed to have been born by a cesarean operation, thus its name; but this is unlikely as at thirty he stated his mother Aurelia was still living. The Italian³¹ laws also made section obligatory, probably due to the warm support of the Roman Catholic Church. In the middle of the eighteenth century, the king of Sicily issued the death sentence against a physician for failure to perform the operation on a dying mother.

Buddha²¹ was supposed to have been delivered from the right flank of his mother. Among the Jews,⁴⁴ according to the Mischnejoth written about 140 B. C., the operation was practised on the living mother. Their Talmud describes two types of operation: the "kariyath habbeten" corresponding to our classical cesarean; and the "yozay dofan" or delivery through the flank. The ancient Egyptians⁶⁰ depicted the operation in their sculpture.

The earliest account of the operation in any medical work is in the *Chirurgis Guidonis*⁵¹ de Cauliaco published in the middle of the fourteenth century (1363). The first authentic case of operating on a living woman was in 1491.⁵¹ Nufer⁵¹ operated in 1500. In 1581, Rousset⁵¹

published a work on the subject, reporting a series of fourteen successful cases. That Shakespeare was familiar with the operation is evidenced by his lines in *Macbeth* where he states that:

"Macduff was from his mother's womb
Untimely ripped."

Pickrell⁵¹ states: "Whatever may have been the origin of the word 'cesarean,' the operation was first called 'cesarean section' by the Jesuit, Theophile Raynaud, in his work '*Deortu infantium contra naturam, per sectionem Cæsarem*,' 1637."

From Shakespeare's time to 1876 the maternal mortality was fearful. Kayser⁵⁵ (Copenhagen, 1844) found a death rate of 62 per cent in eighty years. In 1871, Harris⁵⁵ of Philadelphia collected fifty-nine cases with a 48 per cent mortality. In Great Britain⁵⁵ only four women out of thirty-eight operated on between 1739 and 1845 survived. In France, Gueniot⁵⁵ reported that in Paris only six women survived the operation in the eighteenth century and in the first sixty-nine years of the nineteenth century none survived.

The first authentic cesarean section in the British Isles was performed successfully on Alice O'Neal in 1738 by Mary Donnally,⁵¹ an illiterate midwife. After several attempts to deliver the patient from below, she performed a cesarean with a razor. The incision was to the left of the navel, one inch above and six inches below. She sewed the abdominal wound together with a tailor's needle and common silk, and dressed the wound with a white of an egg. Twenty-three days later the patient was able to walk a mile.

*Thesis read before the Minnesota Academy of Medicine, October 11, 1939.

The first authentic cesarean performed in the United States was done by Dr. Jesse Bennett^s on his wife in 1794. He removed both of her ovaries at the same time. The first recorded operation was performed by Dr. Richmond in Newton,⁵⁷ Ohio, April 23, 1828. The operation was performed in a house with unchinked crevices, without chimney or floor. His only assistants were two women, whose sole duty was to hold blankets to prevent the wind from blowing out the candles. The operation was performed with those few instruments found in a physician's common pocket case. The patient made a rapid recovery and was able to do light housework twenty-four days after the operation.

The first operation of removing the uterus after a cesarean operation was performed in Boston on July 21, 1869, by Professor Horatio Storer.⁶⁹

According to DeLee,¹⁵ Oslander of Goettingen was the first to perform a definitely planned low cervical cesarean section. The latter reasoned that by incising the lower uterine segment, there would be less hemorrhage, that the intestines would not protrude into the wound, and that drainage of the lochia would be directly into the vagina. His first operation was performed in 1805 and his second in 1806. Although both his patients died, he was very proud of his operation and kept one of the bodies to demonstrate the feasibility of the operation to his students. Joerg,³⁷ in 1806, recommended that the uterus be emptied, suprapubically, by approaching the lower segment of the uterus or the upper portion of the vagina from the side. In 1820, Ritgen⁵⁹ attempted to reach the lower segment of the uterus through an incision slightly above and parallel to Poupart's ligament (right), extending from the pubic tubercle to the anterior superior spine of the ilium. The loosely fitting peritoneum was pushed upward until the vagino-uterine junction was reached; this was cut through and delivery was made through the opening. Profuse hemorrhage rewarded his efforts. Baudelocque³ of Neffe in 1823 carried out two similar operations. One of his patients died of hemorrhage and the other peritonitis. In 1870, Theodore G. Thomas⁷¹ and Skene operated according to Joerg's suggested technic in five cases. Three mothers and four children survived. Dr. Thomas²⁶ performed his first operation of laparo-elytrotomy, or gastro-elytrotomy in February, 1870, on a young Irish

multipara who had died of uremic convulsions eight hours previously. Within a month from the time of this experimental operation he describes his second operation upon a living woman but dying of pneumonia, as follows:

"The patient being placed upon a table, anesthesia was produced to the point of quieting her restlessness and jactitation, with a few inhalations of ether. I then passed my hand up the vagina and dilated the cervix slowly and cautiously, so that at a three-quarter distention no injury was done to its tissue. With a bistoury I then cut through the abdominal muscles, the incision being carried from the spine of the pubis to the anterior superior spinous process of the ilium. The lips of the wound were then separated, and by two fingers the peritoneum was lifted with great readiness, so that the vagino-uterine junction was reached. The vagina was then lifted by a steel sound passed within it, and cut, and the opening thus made was enlarged by the fingers. The cervix was then lifted into the right iliac fossa by the blunt hook, while the fundus was depressed in an opposite direction. I then passed my right hand into the iliac fossa and introduced two fingers into the uterus, while the left hand, placed on the outer surface of the uterus, depressed the pelvic extremity of the fetal ovoid. The knee was readily seized, and delivery easily and rapidly accomplished. The child was born alive, but was a badly developed harelippped and, as I before stated, premature infant. It lived for an hour or two, during which time the rite of baptism was administered to it. The mother, the wound in whose abdomen was closed by interrupted suture, died about the same time as the child."

Thomas³¹ operated twice; Skene four times; Charles Jewett of Brooklyn twice; Hime, Edis, Dandridge and Taylor of Cincinnati, and Walter R. Gillette of New York, each once; in all, twelve. Women saved, six; children living but not moribund, seven; bladder lacerated in six cases. In properly calculating the risks of the operation it is fair to exclude the moribund case of Thomas, the intemperate and bedridden one of Hime, and the diseased subject of Edis, who survived, respectively, one hour, two hours, and forty hours. The balance, nine cases, were favorable in four instances and unfavorable in five; six of the nine women recovered, and five children were saved.

Solms⁶⁶ and Dührssen,²¹ to circumvent manual dilatation of the cervix, combined vaginal hysterotomy with the flank incision of Ritgen. Dührssen designated it as the "Buddha Geburt" or laparo-colpohysterotomy. This operation has gained no recognition.

Davis,¹⁴ in 1924, reported twenty-eight cases

done by a modified gastro-elytrotomy technic with two deaths. He made no attempt to open the vagina. (Although at times it was opened where more room was needed.) The bladder was pushed off the lower uterine segment downward and to the left. The denuded area was incised vertically and the child delivered by internal podalic version. He encountered much bleeding in the abdominal wall, and in several of the early cases the uterine wound tore across the right uterine artery. The operation is time-consuming (fifty minutes to two hours), and presents too many technical difficulties which can be easily avoided by a midline incision.

In 1876 Porro⁵³ introduced and recommended the supravaginal removal of the uterus with fixation of the cervical stump extraperitoneally into the abdominal wall. This operation was certainly a life-saving measure in infected cases and would have been employed with increasing frequency but for the introduction by Säger⁶² of his rehabilitated classical cesarean in 1882. Säger's operation enforced rigid asepsis and firm suture of the walls of the uterus, special attention being paid to exact union of the uterine peritoneum as an added barrier to the later leakage of the lochia. Although Kehrer,³⁸ employing a transverse incision of the uterus and suggesting the same improvements in technic as Säger, antedated him by one year, he is rarely given any credit for an excellent piece of work. Kehrer may be called the father of transverse incision of the uterus.

With the employment of Säger's technic the mortality following cesarean section fell rather rapidly from 65 to 5 per cent and lower. Previous to this the uterus had been dropped back into the peritoneal cavity, poorly sutured or at times not sutured at all, dooming the patient to succumb from immediate hemorrhage, or later, to peritonitis.

Although the Säger operation was a great advance in the right direction because of its simplicity, its control of hemorrhage and intraperitoneal leakage, the maternal mortality was very little reduced in the potentially infected or neglected cases. These poor results induced Fritz Frank,²⁴ in 1906, to introduce his suprasymphiseal delivery. He made a transverse incision (Bardenheuer) immediately above the symphysis pubis through the entire thickness of the abdominal wall, and sutured the visceral peritoneum of the

uterus to the parietal peritoneum. The child was delivered through a transverse incision in the uterus. He carried out thirteen such operations with no maternal mortality. Physick⁵⁰ of Philadelphia, in 1822, had recommended a similar operation but had never used it on any subject. Physick thought that the peritoneum could be pushed off the bladder and the anterior wall of the uterus, thus giving space for the delivery of the child without invasion of the peritoneal cavity. Frank found this possible only in part of his cases. Frank's work stimulated Sellheim to extensive anatomic studies of the pelvic viscera in both the pregnant and non-pregnant woman. Sellheim⁶⁵ discovered that the peritoneum was very firmly attached to the bladder at its summit and that this attachment was less firm the farther from the center of the bladder one went laterally. In doing the low cervical operation, Sellheim found it very difficult to go over the top of the bladder sub-peritoneally. He adopted a second plan which was similar to Frank's method of splitting both the parietal and visceral peritoneum transversely, suturing them together with a continuous catgut suture before delivering the child by a transverse incision in the uterus. Sellheim developed a third operation in frankly infected cases which he designated as the utero-abdominal fistula operation. He sutured both the parietal and visceral peritoneum to the skin of the abdominal incision, and after delivery of the child brought the gaping ring of the cervix up and sutured it to the sides of the abdominal incision. In 1910, Sellheim, by further experimenting with the low cesarean, simplified the operation by opening the abdomen longitudinally instead of by a Pfannenstiel incision. Instead of suturing the parietal to the visceral peritoneum, he trusted to laparotomy pads to take care of the peritoneal spill. He incised the vesico-uterine plica transversely, dissected the upper flap up and the lower flap consisting of the bladder downward, made a longitudinal incision in the cervix and delivered the child. This fourth (intraperitoneal) operation of Sellheim is the basis for the low cervical or laparotrachelotomy of DeLee, Franz, Opitz, Krönig, and Beck.

Veit⁷⁷ and Fromme,²⁵ in 1908, developed the transperitoneal extraperitoneal operation. At first they used Frank's method but before uniting the peritoneum they took out the original sutures which joined the parietal to the visceral perito-

neum and closed the peritoneum in accordance with its original anatomical relationship. They later changed the operation by making the incision longitudinal in both the abdominal wall and in the uterus. Clamps instead of sutures were used to unite the uterine to the parietal peritoneum. Hirst³² of Philadelphia, in 1913, independently invented a similar operation. The sutured four layers of peritoneum were brought together in the midline under the fascia of the anterior abdominal wall. Hofmeier,³⁴ in 1908, introduced a similar operation, differing from the above only in that he recommended drainage of the wound.

There were a certain number of operators, however, who were fearful of the infection of the peritoneum by the uterine spill. Sellheim probably was the greatest experimenter along the extraperitoneal lines. Küstner,⁴¹ Latzko⁴³ and Döderlein²⁰ almost simultaneously and independently of one another worked out three ingenious approaches to the lower uterine segment, all of them utilizing the space beneath the bladder, or, perhaps, we had better say the space beneath half the bladder, as the site of the incision in the lower uterine segment through which the child could be extracted.

Newell⁴⁶ favors Küstner's technic. The latter reports 112 cases with only two maternal deaths. He claims that one-half of the cases were potentially infected and unsuited for the classical operation. Newell's description of the operation is as follows:

"The patient (who should be well advanced in labor) is etherized and the abdomen prepared. She is then placed on the operating table in the Trendelenburg position. Unless the bladder is distended with urine, 150 cubic centimeters of sterile salt solution or boric acid are introduced into the bladder. A vertical incision is made just outside the outer border of the left rectus muscle, extending 12 centimeters upward from Poupart's ligament. The deep layer of fascia is incised with care, the object being to expose, but not open the peritoneum. The reflexion of the peritoneum from the abdominal wall to the viscera and the left side of the bladder is now visible. By means of scissors and gauze dissection the left side of the bladder is dissected off from the anterior surface of the lower uterine segment and drawn well beyond the midline by a retractor. The peritoneal reflexion is pushed upward as far as possible and the anterior surface of the lower uterine segment is exposed by retractors. An incision is made in the midline and the child is extracted by forceps. The incision in the lower uterine segment must be very care-

fully made, owing to the extreme thinness of this portion of the uterus, it being never more than a few millimeters thick, as any carelessness may result in cutting the child. The placenta is now removed, the uterine wound is closed in two layers by catgut sutures, and the abdominal wall is closed in layers, except at the lower angle of the incision, a small gauze drain being inserted into the deepest part of the wound.

"The amount of hemorrhage is usually not excessive and is easily controlled. There is always some danger of injuring the bladder and of opening the peritoneal cavity, but if the dissection is made with care neither of these accidents should occur. During the separation of the bladder the left ureter and uterine artery are visible in most cases, and, therefore, should be safe from injury, but carelessness may result disastrously. The employment of the Trendelenburg position during the operation is almost imperative. The operation can be performed in the ordinary dorsal position, but the difficulties are so much increased that neither the operator nor the patient has a fair chance."

Rothrock⁶¹ was an enthusiastic advocate of the extraperitoneal operation and had this to say about it:

"The extraperitoneal operation because of its more difficult technic has never become popular. Yet after one has performed it a number of times and has become acquainted with the anatomy and the details of technic it is comparatively simple and easy.

"The technic employed in the present group, while it departs slightly from the usual routine of the extraperitoneal operation as described by most writers, differs only in a few of the details. The following is a description of the technic employed.

"With the head of the table slightly lowered, a median incision is made in the lower part of the abdomen, beginning 5 or 6 inches above and carried down toward the pubes. The incision is made through the fascia down to, but not through, the peritoneum. The peritoneum is then separated from the abdominal wall to the left of the incision until the left border of the bladder comes into view. After a little experience the border of the bladder can easily be recognized. Many recommend partially filling the bladder with a solution of boric acid before beginning the operation, in order to render its outline more easily recognizable, but I have not found it advantageous, and in some instances it has proved a positive disadvantage, because if the wall of the bladder is thin it renders it more liable to injury. Furthermore, if the bladder is partially filled it takes up more room and is less easily retracted to one side. For this reason I always make it a practice to be sure that the bladder is empty. The separation of the peritoneum from the anterior abdominal wall, owing to its loose attachment, is easily accomplished by peeling it off with a piece of gauze, meanwhile care being taken to avoid injury to the large veins which come into view at the left border of the bladder. The bladder having been located, owing to the loosening of its attachment to the

uterus under the influence of pregnancy, with a piece of gauze it may be easily separated from the uterus and displaced upwards and to the right. This blunt dissection is continued until the median line is approached. The bladder is detached from the uterus well down toward the cervix and upward toward the vesico-uterine plica, until an area of the distended cervical portion of the uterus sufficiently large to permit of an incision adequate for delivery has been uncovered. Great care should be exercised as the vesico-uterine plica is approached to avoid tearing through the peritoneum, which is often quite thin, and should this happen the rent should be immediately closed with a fine catgut suture to prevent contamination of the peritoneal cavity. With the bladder well retracted upward and to the right, the preparation is then complete for uterine incision.

"Instead of a diagonal incision extending upward and outward, as is usually recommended, delivery is accomplished through a median incision. The advantages of the median incision are less hemorrhage and less liability of tearing through the vesico-uterine plica during delivery. In a few instances this will happen even with the median incision, but if the rent is discovered and immediately closed there will be no leakage into the peritoneal cavity. With increasing experience the occasional unavoidable tearing through the peritoneum will happen less frequently. With the cervical portion of the uterus laid bare, an incision of sufficient length to permit easy delivery is made in the median line over the presenting head. The amount of bleeding varies greatly; in some the venous sinuses of the uterine wall are enormously distended, while in others the incision leaves an almost bloodless field. For the control of hemorrhage in the uterine wound, which is sometimes profuse, specially adapted triangular clamps are lightly applied over bleeding sinuses, as in all other types of operation. With the aid of the suction apparatus the field of operation may be kept fairly clear of fluids and blood until after delivery, when hemorrhage usually ceases spontaneously. . . .

"Before proceeding to deliver, it has long been my practice to first rotate the occiput anteriorly, regardless of the position in which it may be found, and to hold it in position with the left hand while the blade of the forceps is slipped under it, which will hold it in position until the other blade is applied. This secures the most favorable position for delivery and, besides, the blades of the forceps, on account of their shape, fit better when applied to the sides of the head and are much less likely to cause injury. . . . The application is made exactly as in vaginal application, with the pelvic curve directed upward.

"It is very desirable to make the uterine incision of sufficient length, otherwise considerable resistance to delivery may result, as well as irregular lacerations which may even extend upward through the vesico-uterine plica. Such lacerations are to be avoided, if possible, as accurate coaptation of the wound is more difficult, and imperfect union may result. . . .

"After delivery has been accomplished here, as in all

sections, I have adopted a conservative plan for the management of the third stage. Immediately following delivery pituitrin and ergot are given hypodermically. As the placenta is still attached, one may now safely wait until the uterus regains its tone. It is my custom to wait, if necessary, for ten to fifteen minutes, and it frequently happens that the uterine contractions will detach and even sometimes expel the placenta. In case this does not happen, a little gentle massage over the fundus will stimulate the uterus to contraction, frequently with the desired result. In case of failure of the uterus to detach and expel the placenta it is sometimes necessary to separate and deliver it manually, but this is always postponed until the uterus has regained its tone and is well contracted. Here, as in the classical section, if the cervix is uneffaced and undilated, it is then slightly dilated with a uterine dilator from above. . . .

"The placenta having been delivered, the edges of the uterine wound are grasped with volsella forceps at both ends of the incision in order to facilitate the placing of the sutures. The incision is closed by three layers of sutures, the first a continuous suture of fine catgut to approximate the endometrial edges, care being taken to avoid the endometrium. The second layer of interrupted sutures of chromicized catgut, which include the greater part of the thickness of the uterine wall, are then placed. Care is exercised in tying these sutures to avoid excessive tension and strangulation of the tissues; only sufficient tension to approximate the edges should be used. Another continuous suture of fine catgut to neatly approximate the outer edges of the wound completes the closure of the uterine incision. If there is still oozing, perfect hemostasis is secured by ligating all bleeding vessels. The uterovesical fold is carefully examined for possible rents and the bladder is restored to its normal position and its left border attached by a couple of catgut sutures to hold it in place. While the wound is large, if hemostasis is complete, drainage is unnecessary. . . .

"The advantages of the operation are safety and freedom from pain and discomfort following the operation. This feature must be witnessed to be appreciated. Quite frequently patients suffer no more discomfort following delivery by this operation than after a normal delivery, and are able to take nourishment immediately after the effects of the anesthetic have passed. It is moreover free from postoperative complications, especially meteorism and ileus. The operation does not prevent subsequent deliveries by the same operation. In a number of cases a second or even a third operation has been made in the same field without difficulty and no abnormal adhesions have been encountered following previous operations. . . .

"From time to time discussion has arisen over the question as to whether the operation is easier after labor has progressed and the head has engaged, and the statement has been made that early in labor or before the onset of labor the operation is more difficult, because at this time the lower uterine segment is not distended. According to my experience, there is little

difference and, if any, it is in favor of the early operation before the head has engaged and has become impacted. . . .

"Forty-four cases were delivered by the extraperitoneal operation and as familiarity with the technic increased the scope of application of the operation extended, until the latter part of the period it came to be the operation of choice. Of the forty-four cases, nineteen were elective and in twenty-five it was performed after labor had been in progress for some time, as, for example, in nineteen after the test of labor in doubtful borderline cases, in two after the induction of labor with the bag, and in four after an attempt had been made to deliver with instruments. In two of the latter, labor had been induced by the bag.

"There were no maternal deaths and only one still-birth. . . ."

The above description follows very closely the technic ascribed to Latzko, which the latter reported rather meagerly in the *Wiener Klinische Wochenschrift* of April 8, 1909.

After a careful study of the different extraperitoneal operations, Jellinghaus⁶⁸ selected the Latzko technic for use in the New York Lying-In and the Nursery and Child's Hospitals. Since 1923 he has acted as instructor to most of the men using this operation in these hospitals. In 1930, Steele⁶⁸ reported a study of fifty-nine cases done by the Latzko method from the Lying-In Hospital, with five maternal deaths, a mortality of 8.5 per cent. The average number of hours in labor was twenty-eight and one-half, the average number of hours after the rupture of the membranes was twenty-one and one-half.

Burns⁹ reported a series of nine Latzko operations at the New York Nursery and Child's Hospital with no maternal deaths.

In 1937, Aldridge¹ reported an interesting modification of the Latzko operation. He describes this modification as follows:

"A study of the anatomic structures around the bladder shows that its musculature is completely surrounded by a thin but definite layer of endopelvic fascia. After incising the abdominal wall, the first step in dissection is to open the layer of endopelvic fascia, covering the anterior surface of the distended bladder by a longitudinal incision in the midline. After this layer has been incised, the bladder can easily be displaced from within its endopelvic fascial capsule on the left side by blunt dissection. As soon as the anterior surface of the lower uterine segment is reached, the layer of endopelvic fascia on the posterior surface of the bladder can readily be seen as a smooth glistening layer. It has been found that this layer can be immediately opened and dissection can more readily be

continued behind the layer rather than making further attempt to free the bladder from its fascial capsule. When dissection is continued between this layer and a similar layer covering the musculature of the lower uterine segment, it will be found that a free, practically bloodless, space has been entered and that the anterior surface of the lower uterine segment can readily be exposed. Between these fascial planes the dissection can easily be carried beyond the upper border of the bladder. This is exactly the same almost bloodless space which is entered in displacing the bladder downward in doing the so-called "low flap" cesarean section by the abdominal route."

When the space bared seemed to be too limited to permit delivery without tearing the uterovesical fold of peritoneum, the latter was incised and the freed peritoneal margins were carefully sutured together. The uterus was then opened by a median incision. In addition to drainage of the abdominal incision, a small cigaret drain was placed between the bladder and the lower uterine segment. The drain passed into the vagina from the lower angle of the cervical wound.

Sellheim,⁶⁵ following his excellent anatomical studies of the extraperitoneal approach to the lower uterine segment, admonished one to keep close to the midline. He stated, "Je weiter man nach aussen geht, um so ungünstiger werden die Verhältnisse." DeLee,¹⁵ in discussing the extraperitoneal cesarean, says: "It has been learned by bitter experience that the further one advances from the midline the greater grow the dangers of hemorrhage and the more technically difficult each step of the operation becomes."

With this idea of keeping in the "midline" paramount, the writer for some years has used the following technic in reaching the lower uterine segment extraperitoneally:

The patient is placed in a moderate Trendelenburg position. About 100 c.c. of sterile boric acid solution are injected into the bladder through a large rubber catheter which is clamped off and left in situ. A midline incision is made from about 5 centimeters below the umbilicus to the symphysis. This incision extends downward to but not through the fascia except at its lower angle. Immediately above the symphysis the fascia is incised longitudinally for a distance of 5 centimeters. One thus enters the space of Retzius, which anatomically extends from the front of the bladder to the umbilicus, limited laterally below by the hypogastric and above by the inferior epigastric arteries.

Keeping this anatomical fact in mind, the parietal peritoneum is freed from the overlying abdominal fascia, from the space of Retzius upward for two-thirds of the distance to the umbilicus and laterally almost to the outer borders of the recti muscles. The fascial incision is now completed, extending upward to within one-half centimeter of the superior border of the freed peritoneum. This freeing of the abdominal parietal peritoneum allows the bladder to be pulled downward slightly. Under gentle traction the prevesical fascia is incised transversely near the bladder summit. The bladder is easily "shelled out" of its endopelvic (prevesical) fascial envelope and is pushed directly downward in the midline. To provide more room and to lessen the liability of injury to the bladder, the previously injected boric acid solution is now allowed to escape from the inlying catheter. The endopelvic layer of fascia lying behind the bladder (and in front of the lower uterine segment) is now incised transversely for a distance of 4 to 6 centimeters. The lower fascial flap containing the bladder is pushed downward and the upper flap upward. Great care must be exercised in manipulating the upper flap. Separation is much easier if the patient has been in labor several hours. A median incision 9-10 centimeters in length is made in the bared area of the lower uterine segment and the head is extracted slowly and gently with obstetrical forceps. After spontaneous expulsion or manual removal of the placenta, the uterine incision is closed with three layers of continuous chromic catgut sutures. The bladder is allowed to drop back over this suture line. The transverse incisions in the endopelvic fascia are closed by a few appropriately placed interrupted plain catgut sutures. Sterile boric acid solution is again injected into the bladder through the catheter to demonstrate any rents, which, if found, are immediately repaired. The abdomen is closed in layers with a cigaret drain placed in the lower angle of the wound. It is recommended that the operator stand on the right side of the patient, which position facilitates both the dissection of the peritoneum off the abdominal wall from below and the application of obstetrical forceps.

Aside from technical difficulties, which to some men seem to be insurmountable, the main objection to the different extraperitoneal operations lies in the frequency of injuries to bladder and

ureters. For that reason a certain number of men prefer the transperitoneal-extraperitoneal operation of Fromme²⁵-Veit,⁷⁷ or Hirst,³² as previously described in this paper.

The Gottschalk⁴²-Portes⁵⁴ operation with very little stretch of the imagination may be classified as an extraperitoneal operation. It is a cesarean section followed by a temporary exteriorization of the uterus. It is a two-stage procedure. The first stage consists in delivery of the pregnant uterus through a long abdominal incision. The abdominal wall is sutured around the uterus at the level of the cervix. A high incision is made in the fundus, as in the regular classical cesarean. The child, placenta and membranes are extracted. The incision is sutured in layers. The uterus is covered with moist packs and allowed to remain on the abdomen.

In the second stage, if the patient demonstrates uncontrollable sepsis, the uterus is amputated extra-abdominally by the Porro technic as soon as her condition warrants; however, if the patient is not too septic, the uterus is allowed to involute outside the abdomen and in twenty to thirty days, the adhesions are freed and it is returned to the peritoneal cavity.

DeLee¹⁶ suggests that the uterine wound be left unsutured, insuring better drainage. The objection to the operation is the prolonged hospitalization.

Gottschalk⁴² of Berlin described this operation in 1909 and 1911. Portes⁵⁴ of Paris, in ignorance of Gottschalk's work, reported his operation in 1924. A. Couvelaire,¹³ in 1925, reported thirty-two cases in which the Portes operation was used, with two deaths, or a mortality of 6.5 per cent. Phaneuf⁴⁸ reported a Portes cesarean with recovery in 1927. DeLee,¹⁶ in the 1938 edition of his textbook, states that up to 1935, 220 cases of the above operation had been reported, with a mortality of about 20 per cent.

As stated previously in this paper, the two-flap low cervical operation of DeLee^{17,18} or of Beck^{4,5,6} is a modification of Sellheim's number four low cervical operation. Many men think that this operation is technically much more difficult than the classical operation, and that it is too time consuming.

Falls²² in an analysis of fifty-seven cases of low cervical as compared with fifty-seven cases of the classical operation, done by himself, under

as nearly as possible similar operating room conditions, reached the following conclusions:

"1. As regards morbidity and mortality in the series, there appears to be a slight difference in favor of the low cervical operation.

2. As regards postoperative vomiting, ileus and temperature days, hospital days and wound infection, there appears also to be a corresponding slight difference.

3. There seems to be no difference in the postoperative discomfort.

4. There seemed to be less bladder dysfunction after the low cervical than after the classical operation.

5. There is no appreciable difference in the technical difficulty as measured by the operating time.

6. The results obtained by the low cervical operation are hardly so superior to those following the classical operation as to justify the extravagant praise of some of its sponsors."

When, from the desperate condition of the patient, speed in operating is imperative, Krönig's⁴⁰ low cervical operation is recommended. A transverse incision is made in the loose visceral uterine peritoneum about one centimeter above the vesico-uterine fold. The bladder is easily pushed off the lower uterine segment by blunt dissection. The bared area of the latter is incised longitudinally, the child is extracted by forceps and following spontaneous expulsion or manual removal of the placenta the uterine wound is sutured by continuous or interrupted chromic catgut sutures. The bladder is sutured over the uterine wound. Krönig⁴⁰ considered the peritonealization of the classical cesarean wound inadequate protection against leakage of septic material from the infected interior of the uterus or the uterine wound into the general peritoneal cavity, and thought that the overlying bladder would prevent this.

Beck⁶ claims his double flap operation is a modification of the Krönig operation. DeLee¹⁵ considers his and Beck's low cervical operations modifications of the Sellheim number four operation. Their operations are quite similar. They both incise the loose uterine peritoneum transversely half way between the bladder reflection and the gray seam (plica). They dissect up two flaps of peritoneum, an upper and a lower. The upper flap is made by gently passing a pair of blunt scissors, or fingers, under the peritoneum. The lower flap is formed by stripping the bladder off the anterior surface of the uterus by blunt dissection as in abdominal hysterectomy. The denuded area is incised longitudinally and the child is extracted with forceps. After re-

moval of the placenta, the uterine incision is closed by two or three layers of continuous or interrupted catgut sutures. The upper peritoneal flap is brought down and sutured over the superior portion of the closed uterine incision. The lower flap, containing the bladder, is pulled up and sutured to the uterine peritoneum about one centimeter above the original incision. Beck⁷ has modified his first operation by leaving an island of undenuded peritoneum about one centimeter wide between the two flaps to which they are sutured, with only slight overlapping.

Beck^{4,5,6} and DeLee¹⁷ are strong advocates of the above operation. DeLee¹⁷ in 1925, reported 390 cases by his technic with three maternal deaths, a mortality rate of 0.76 per cent. Greenhill²⁷ in 1929 reported 731 low cervical cesareans performed at the Chicago Lying-In Hospital, with nine deaths, or a mortality rate of 1.2 per cent.

Beck,⁷ in 1929, Montgomery⁴⁵ in 1936, and Quigley⁵⁵ in 1937, have analyzed in the accompanying tables the mortality rates of the classical as compared to the low cervical cesarean.

Phaneuf,⁴⁹ in 1936, reported 515 personally observed cases of the lower cervical operations (in 292 the transverse uterine incision, of which he is a strong advocate, was used) with an uncorrected mortality of 4.2 per cent. Many of the cases had been given a test of labor of six or more hours.

Phaneuf⁴⁹ is a vigorous proponent of the transverse uterine incision. The objections to the above incision are: (1) there is more bleeding; (2) there is danger of the incision tearing across the uterine artery or the ureter; (3) the upper incised portion of the uterine wound retracts and thickens, while the lower portion remains thin, which renders accurate suture difficult; (4) and if pus collects back of the peritoneal flaps under the bladder, the incision is too high to be readily reached and drained through the cervical canal.

Beck⁵ thinks that in the infected classical cesarean cases, general peritonitis develops because of a massive spill of infectious material into the peritoneal cavity from the interior of the uterus through a broken down uterine incision. He considers the double flap operation a barrier against this occurrence, and if pus forms under the flaps, it will drain through the cervical wound into the vagina. DeLee¹⁷ is of a like opinion.

CESAREAN SECTION—BARRY

CESAREAN SECTION AFTER SIX HOURS OF LABOR IN THIRTY-FOUR BROOKLYN HOSPITALS (BECK)

Hours in Labor	Classic Operation				Low Operation			
	No Vaginal Examinations		Vaginal Examinations		No Vaginal Examinations		Vaginal Examinations	
	Cases	Deaths	Cases	Deaths	Cases	Deaths	Cases	Deaths
6-12	89	5	48	4	13	0	7	0

Total cases	472 with 43 deaths; 12.3%				123 with 7 deaths; 5.6%			

Other factors may explain the better results of the low cesarean. Hofbauer,³³ in a histological study of forty-three uteri removed at different times during pregnancy and labor, concludes: "During pregnancy a phagocytic tissue, consisting of monocytes and clasmatocytes, makes its appearance in the base of the broad ligament, and is intensified by the stress of prolonged labor, but particularly by the existence of infection. . . . The presence of this phagocytic tissue in the parametrium must be regarded as a prophylactic biological reaction and as a marked protection against infection."

Schilling⁶⁴ states:

"It is a well established fact that tissues exposed more or less constantly to infection will develop and exhibit a corresponding degree of resistance to microbic invasion. And, it is well known, too, that in parts of the body well protected from every form of contamination, such as the mediastinum, for instance, the tissues exhibit a comparatively low degree of immunity against infection.

"So the tissues of vagina and cervix accustomed to battling infection have developed a substantial degree of resistance to bacterial invasion.

"This circumstance will explain why lacerations of the cervix and abrasions in the vagina so comparatively seldom result in dangerous infection. On the other hand, the cavity of the uterus is normally sterile. Consequently, its resistance to infection is comparatively low. So that in this location bacteria may exhibit great virulence, which in the lower birth canal are quite innocuous."

The smaller operative blood loss in the low cervical as compared to the classical cesarean, may contribute in no small degree to the smoother convalescence of the patient. This is particu-

EFFECT OF ABDOMINAL CESAREAN SECTION THE PUERPERAL MORBIDITY AND MATERNAL MORTALITY OF CESAREAN SECTION IN DISPROPORTION CASES (MONTGOMERY)

1. Classical elective cesarean section.	
Maternal mortality	1 in 110 = 1.9%
Puerperal morbidity	51 in 110 = 46.0%
2. Classical cesarean section, section after less than 12 hours of labor.	
Maternal mortality	0 in 15 = 0.0%
Puerperal morbidity	8 in 15 = 53.0%
3. Classical cesarean section, section after more than 12 hours of labor.	
Maternal mortality	3 in 38 = 8.0%
Puerperal morbidity	24 in 38 = 63.0%
4. Low cesarean section	
Maternal mortality	1 in 28 = 3.5%
Puerperal morbidity	18 in 28 = 64.0%
Total mortality rate for cesarean section in disproportion	5 in 191 = 2.6%

QUIGLEY'S COLLECTION OF 11,994 CASES

	Cases	Deaths	Rate
Classical Cesarean.....	5,757	325	5.6
Low Cervical.....	3,700	66	1.78

Rochester General Hospital (Low cervical).....	264	1	0.3
	11,994	526	4.38%

larly evident in those patients who have been in labor several hours. The lower uterine segment is markedly thinned out and bleeds but scantily when sectioned. It is almost a truism that the thinner the cervical zone the less the bleeding.

Greenhill²⁷ and others claim that the presence of the wound in non-contracting or quiet zone of

the uterus lessens the tendency to postpartum hemorrhage and favors better healing, thus minimizing the danger of rupture in subsequent pregnancies.

In any consideration of the various types of cesarean section, it must be clearly realized that the time element is by far the most important factor in controlling the mortality rate. No matter how skillful or experienced the operator, no type of operation devised by the ingenuity of man will save the prospective mother from a septic death, if it is done at an unfavorable time.

The maternal mortality is lowest where the operation is carried out before the onset of labor. Even at this favorable time the basic mortality varies from 0 to 2 per cent, and the danger of the operation increases progressively with the advance of labor. Holland^{35,36} gives the following illustrative findings in 1,953 sections for contracted pelves:

Time of operation	Number of cases	Mortality per cent
A. Before labor	1202	1.6
B. Early in labor	389	1.8
C. Late in labor	220	10.0
D. After induction of labor	35	14.0
E. After attempt at delivery by forceps or craniotomy	107	27.0
Total	1953	4.3

Stander⁶⁷ considers the classical cesarean unsafe after labor has been under way for more than six hours. Peckham's⁴⁷ analysis shows a rapid rise in morbidity and maternal mortality after twelve hours of labor.

Histological and bacteriological investigations, as well as clinical experience, prove that the uterus is frequently infected after a prolonged labor. The factors which influence bacterial invasion of the uterus during labor are: (1) vaginal examinations; (2) time of rupture of the membranes; (3) duration of labor; and (4) intra-uterine manipulations.

Harris and Brown³⁰ in a study of fifty cases during labor found positive cultures in twenty-two, thirteen of which had not been examined vaginally; also of the twenty-two patients with positive cultures, seven were infected despite unruptured membranes.

In twenty-nine patients who had been in la-

bor less than six hours when cesarean was done, cultures were sterile in twenty-eight; in the one showing positive culture, although not in labor, the membranes had been ruptured for ten hours. In fourteen of twenty-two infected cases the temperature was normal; the remaining eight patients show elevations of temperature, but two of these were less than 100 degrees F.

From this investigation, Harris and Brown³⁰ concluded that the uterus was free of bacteria at the end of pregnancy and also during the first few hours of active labor, and that the probability of ascending infection increased with each hour of labor. Their investigations justified the conclusion that ascending infection is probably the most important factor in the causation of the high mortality rate following cesarean section. This ascending infection occurred in the presence of unruptured membranes, and the absence of temperature was no certain criterion that the patient was not infected.

The incidence³⁹ of cesarean section in the United States averages 2.9 per cent. This is far too high an incidence, leaving us with a maternal mortality rate which startles the rest of the civilized world. To correct this high cesarean rate and indirectly reduce our mortality rate, several suggestions are ventured:

Pay closer attention to pelvic measurements. Realize that external measurements have little value unless one takes accurate internal measurements and also learns to palpate the bony pelvis. Carefully check the above with expert pelvic x-ray measurements, as suggested by Thoms⁷²⁻⁷⁶ and later by Caldwell and Moloy.^{10,11,12}

Observe the patient closely in the last month of pregnancy and determine whether the head will enter the pelvic inlet readily. Try to learn when the head is moldable or not by its consistency.

Have a clear conception of what is meant by a trial of labor or the test of delivery. Is the given pelvis too small to venture a test of labor? A trial of labor means allowing the patient to enter labor and closely watching to see if the cervix will dilate, if the head will fix itself in the inlet, and, if fixation occurs, will it engage, as evidenced by the presenting part reaching the level of the ischial spines. A real test of delivery means four to six hours of hard pains every three to six minutes after complete dilation of the cervix with the membranes ruptured.

Besides a contracted pelvis, tumors blocking the birth canal may remain unrecognized until so late in labor that a classical cesarean would be too hazardous. The situation or the size of the tumor may render any of the so-called low cervical or extraperitoneal operations impossible. A pelvic examination early in pregnancy might easily prevent the occurrence of such tragic situations.

A prolapsed cord or arm may be too badly infected for delivery through the general peritoneal cavity. However, delivery by the extraperitoneal or transperitoneal-extraperitoneal route may be comparatively safe for the mother, thus avoiding sacrifice of the child.

Too many patients are sectioned for a suspected contracted pelvis, whereas, if careful pelvic studies were made, it would be clearly realized that the pelvis was of ample size, but that a cervical dystocia was the real cause of the prolonged labor. Many patients entering the hospital for delivery are not in true labor, but are experiencing a preliminary period which may ensue before the development of actual labor. Hamilton²⁸ has shown that in 539 primiparae, 375 had a preliminary period of fifteen hours and fifty-one minutes; in 461 multiparae, 306 had a preliminary period of fifteen hours and seven minutes. It would seem ridiculous to section a woman, in the preliminary stage of labor, for dystocia.

Contracted pelvis are not common in the United States, and Dewees¹⁹ wrote in 1828 that he had met only three cases in his large experience. Reynolds,⁶⁶ in 1890, reported an incidence of 1.34 per cent of contracted pelvis in a series of 2,227 women delivered in Boston. In 1897, Flint²³ reported an incidence of 8.46 of contracted pelvis in 10,233 patients delivered at the New York Lying-In Hospital. Williams,⁷⁸ in a series of 11,630 women delivered at the Johns Hopkins Hospital, found that 3,100 of them presented a contracted pelvis of some type. In this series the incidence of contraction of the inlet was 8.96 per cent in the white, and 37.31 per cent in the negro women. Six per cent of the series showed a contraction of the outlet, *i.e.*, an intertuberous diameter of 8 centimeters or less. Reports from larger clinics showed that 69 to 81 per cent of these women will deliver spontaneously if labor is conducted properly. Stander⁶⁷ gives an incidence of spontaneous delivery of 81.75 per cent;

Valency 69 per cent; Peham 72.4 per cent; Bar 76.5 per cent; Bürger 77.8 per cent; Krönig 78.5 per cent; and Baisch 80 per cent.⁶⁷

Schauta,⁶³ in 49,397 deliveries, found 5,288 contracted pelvis, an incidence of 10.7 per cent. Of these women 77.8 per cent with contracted pelvis delivered themselves spontaneously with only four maternal deaths, or a maternal mortality of .09 per cent, which would seem to prove that the best that can happen to a woman with a contracted pelvis is to be allowed to deliver spontaneously.

Classical cesarean, at the time of election, should be reserved for those patients who, after careful study, demonstrate clearly their inability to deliver spontaneously; in the border line cases, if after a trial of labor of not much more than six hours, there is no progress, the low cervical operation of DeLee,¹⁷ Beck,⁴ or Krönig⁴⁰ is recommended; if labor has continued for twelve hours, or if the membranes have been ruptured for more than four hours, and the patient is not exhausted and presents a normal temperature and pulse, one of the various types of transperitoneal-extraperitoneal or a real extraperitoneal operation should be the operation of choice.

In contemplating any type of cesarean operation, it must be clearly realized that puerperal infection is a wound infection. One must hesitate to place a wound in the uterus and soft tissues in the presence of an existing infection, as evidenced by a high temperature, rapid pulse and foul vaginal discharge. Even a pubiotomy should not be considered (which facilitates delivery best where there is a contraction of the outlet); only a craniotomy will give the woman her greatest chances of survival. For religious reasons or because of a great desire on the part of the parents for a child, one might consent to undertake a Porro operation in the face of an existing infection. But it should be clearly explained to the patient that the mortality of the above operation averages from 1.56 (John W. Harris)²⁹ to 17.4 per cent (Eardley Holland).³⁶ Facing the same circumstances in a young woman, in order to save the uterus, one might give serious consideration to the Gottschalk-Portes operation (mortality 20 per cent, DeLee).¹⁶

In summing up the question of which type of cesarean section to employ, it must be clearly realized that the ideal operation is one that offers

the greatest safety to the patient and is technically not too difficult for the average surgeon. The low cervical operation according to the technic of Krönig,⁴⁰ Beck,⁶ or DeLee¹⁷ seems best to meet these requirements. If one fears the peritoneal spill encountered in this operation, and is technically competent, he may approach the uterus extraperitoneally; if not technically competent, it is recommended that he employ the simpler technic of the Fromme,²⁵ Veit,⁷⁷ or Hirst³² operation.

From the statistics quoted in the above paper, it appears clearly evident that the borderline case can be given a longer trial of labor with a far greater margin of safety to the patient when any of the various types of low cervical operation are employed than with the classical cesarean.

Finally, the obstetrician and surgeon must be keenly awake to the fact that it is clear thinking rather than expert operating which, in general, offers the greatest chances of recovery to the patient; an exhausted or a frankly infected subject is a poor risk for any type of operative procedure, whether it be a craniotomy, pubiotomy, a Porro cesarean or any of the various types of low cervical or extraperitoneal cesareans described in this paper.

FURTHER RESULTS IN THE TREATMENT OF ACUTE POLIOMYELITIS WITH ANTISTREPTOCOCCIC SERUM* (1928-1937)

EDWARD C. ROSENOW, M.D.

Rochester, Minnesota

IT has been conclusively demonstrated time and again that the inciting agent of acute epidemic poliomyelitis is a filtrable virus as now understood. Studies of the virus have yielded information of great value regarding the pathogenesis of this disease but these studies, it can truly be said, have yielded little of practical value for specific prevention and treatment and little information as regards the source of the virus. Convalescent serum could not solve the problem because the disease would have to continue to occur in virulent form, with its dire consequences, in order to insure a supply. Virus vaccines containing cord tissue obtained from monkeys that had succumbed to poliomyelitis could not be prepared in sufficient amount for general use.

Impressed by the early work on the streptococcus (1916) when Towne, Wheeler and I first demonstrated it in and isolated it from the nasopharynx and the lesions in the spinal cord of human beings and monkeys that had succumbed to poliomyelitis, I have continued to study this dis-

ease by special methods from the point of view of both the streptococcus and the virus in the hope that effective methods for specific prevention, diagnosis and treatment might be found. Reports of results on different phases of the problem,^{3,7,8,10,12,15} including treatment of the disease with the antistreptococcic serum,^{5,6,7,11,13,14} have been made from time to time. The results of treatment of the disease with the antistreptococcic serum have been corroborated by independent observers.^{1,2,4,16,17}

A comprehensive review of this work, together with important unpublished data, will be published elsewhere. Suffice it to state at this time that all reasonable requirements for establishing the causal relationship between the streptococcus and this disease now have been fulfilled, including the demonstration of streptococcal antigen in the serum of patients and monkeys during the acute stage of the disease and demonstration of streptococcic antibodies during convalescence, and the making of the virus from the streptococcus.⁹

Monkeys have been immunized against the vi-

ACUTE POLIOMYELITIS—ROSENOW

TABLE I. RESULTS: TREATMENT OF ACUTE POLIOMYELITIS WITH ANTISTREPTOCOCCIC SERUM: 221 PATIENTS RECEIVING SERUM AND 116 PATIENTS NOT RECEIVING SERUM

Groups	Patients	Deaths		Patients*	Residual paralysis				
		Number	Per Cent		None	Slight	Moderate	Severe	
								Number	Per Cent
Serum given	221	10	4.5	211	161	29	14	7	3.3
Serum not given (controls)	116	23	19.8	93	34	10	17	32	34.4

*Patients out of 221 who received serum and survived and those out of 116 who did not receive serum and survived.

rus of poliomyelitis with vaccine prepared from the streptococcus. Serum obtained from horses immunized with the streptococcus has been shown to neutralize the virus and to have curative action on poliomyelitis among monkeys and human beings.^{7,11} The results of the intradermal injection of the antistreptococcic serum and the precipitation test performed with this serum, and the serum of patients, have been shown to be diagnostic of poliomyelitic infection, especially early in the prepoliomyelitic and preparalytic stages of the disease.¹⁰ It is the purpose of this paper to record additional results achieved by the use of antistreptococcic serum in the treatment of acute epidemic poliomyelitis.

This paper is composed of, first, results obtained in the treatment of patients who have received the serum since 1928 under my supervision and under the supervision of physicians to whom I sent the serum at their request; and second, effects of the disease among patients who lived under conditions comparable to those of the first group, and who had attacks of similar severity at about the same time during the same outbreaks of the disease, but who did not receive the serum. Results in the course of the disease among the two groups of patients are compared. The results observed by attending physicians were recorded and reported in the form of answers to a questionnaire sent with each lot of serum. Only cases in which information left no reasonable doubt as to the correctness of the diagnosis of acute poliomyelitis were considered.

Altogether, cases representing 337 patients were available for analysis; in 221 of these serum was administered and in 116 serum was not administered (Table I). Of the 221 patients who received serum, 137 were males and eighty-four were females. Of the 116 patients used as controls, seventy-seven were males and thirty-nine

were females. The ages in the two groups were comparable. The initial symptoms in the group in which serum was administered were somewhat more severe than the initial symptoms in the control group.

Thus, the initial symptoms for 188 patients of the group in which serum was administered were considered to be severe in seventy-nine instances (35.7 per cent), moderate in eighty-two (37.1 per cent) and mild in twenty-seven instances (12.2 per cent). The initial symptoms for ninety-three patients of the group of controls were considered to be severe in twenty-seven instances (28 per cent), moderate in forty-two (45 per cent) and mild in twenty-four (26 per cent). Since protocols of individual patients to whom treatment with serum was administered have been reported previously,⁶ they are omitted from this report.

In view of the fact that many patients were treated and reported on by physicians with limited experience in the treatment of poliomyelitis, I have summarized the results according to the two most important consequences of this disease, death and residual paralysis, in Table I. Errors in judgment as regards minor effects observed were thus almost wholly eliminated. Moreover, in order to eliminate other possible criticism, all patients who received serum were included, regardless of the amount, or the time of the administration, of the serum after the onset of symptoms and regardless of the condition of the patient.

Of 221 patients who received the serum, ten (4.5 per cent) died, whereas of the 116 control patients who did not receive serum, twenty-three (19.8 per cent) died. Of the 211 patients who had received serum and who survived, 161 recovered without having residual paralysis, twenty-nine had slight paralysis, fourteen had moderate residual paralysis and only seven (3.3 per

cent) had severe residual paralysis. In contrast, of ninety-three patients in the group of controls who survived, only thirty-four did not have residual paralysis, ten had slight paralysis, seventeen had moderate paralysis and thirty-two (34.4 per cent) had severe residual paralysis.

The serum was injected intramuscularly once or twice daily in amounts ranging from 5 to 20 c.c., depending on the age of the patient, severity of symptoms and results obtained. The serum used consisted of one part of the centrifugated euglobulin (bacterial-antibody) fraction of the antiserum of horses hyperimmunized with the heat-killed poliomyelitic streptococcus, dissolved in nine parts of physiologic salt solution rendered 0.2 per cent phenol. The euglobulin was precipitated by diluting one part of whole serum with nine parts of slightly acidulated distilled water. Only strains of streptococci freshly isolated from the nasopharynx, spinal fluid or brain and spinal cord of human beings and from the spinal fluid or brain and spinal cord of monkeys that had succumbed to poliomyelitis—that is, only strains that had “neurotropic” cataphoretic velocity and that produced flaccid paralysis in rabbits—were used for the immunization of horses. These strains were kept in a dense suspension of two parts of glycerol and one part of a solution of 25 per cent sodium chloride throughout the period of immunization. The serum was obtained from horses after the content of antibodies had become high, and usually after one to five years of weekly intravenous injections of the streptococcus.

In 188 of the 221 patients to whom serum was administered, the number of injections and the total amount of serum administered were recorded. To these patients, a total of 508 injections was administered, representing 7,670 c.c., or an average of about 15 c.c. at each injection, and 40 c.c. for each patient. The amount of serum administered per patient ranged from 10 c.c. to 200 c.c. Forty-nine patients received only one injection of 10 c.c. or more, nine received two injections which were twelve to twenty-four hours apart, thirty-one received three injections, twenty-eight received four injections, twenty-six received five injections and twenty-three received six injections or more. The incidence of immediate and late reactions to the serum was obtained in the treatment of 153 patients. Only one person had an immediate severe reaction to the

serum, three had a moderate reaction, three a slight reaction and 146 had no immediate reaction. Six patients had severe late reactions, fifteen had moderate reactions, twelve had slight reactions and 120 did not have a late reaction.

Of the ten patients who died in the group that received serum, all had marked paralysis before the serum was administered. The serum was administered to three patients on the second day of illness, to four on the third day and to three on the fourth day. In five of these patients respiratory paralysis had developed before the first dose of serum was injected. Seven patients were adults twenty to forty-eight years old, one was fifteen years old, one was twelve and one was three and a half years old. The number of cells in the spinal fluid of six patients who died ranged from 30 to 640; the average was 517 cells. Severe symptoms characterized all patients from the onset of the disease.

Of the seven patients to whom serum was administered and who recovered with severe residual paralysis (Table I), five had severe paralysis before treatment with serum was instituted and two had moderate paralysis. In only one instance was the first injection made as early as the second day after the onset of symptoms; in two, on the third day; in two, on the fourth day, and in two on the seventh day. The number of cells in the spinal fluid of four of these seven patients ranged from ten to 250 cells; the average was 139 cells. The ages of these seven patients ranged from one and a half years to twelve years and averaged four years. The average time of the first injection of serum was 4.7 days after the onset of symptoms.

Of the twenty-nine patients who had slight residual paralysis after treatment, twenty-one had a severe degree of paralysis and two did not have any paralysis at the time of the first injection of serum. The number of cells in the spinal fluid of seventeen patients ranged from thirty-one to 329; the average was 126 cells. The ages of the patients ranged from six months to forty years, and averaged ten years. The average time of the first injection of serum after onset of symptoms was 3.5 days.

Of the 161 patients who eventually recovered without residual paralysis, 106 did not have paralysis, eight had slight paralysis, six had moderate paralysis and forty-one had severe paralysis, at the time of the first injection of serum. The

ages of patients in this group ranged from six months to twenty-seven years, and averaged 8.2 years. The number of cells in the spinal fluid of 100 patients ranged from eleven to 800 cells; the average was 146 cells. The average time of the first injection of serum after the onset of symptoms was 2.3 days.

Comment and Summary

The results of treatment with poliomyelitis antistreptococcic serum of an additional series of patients suffering from poliomyelitis are reported. The severity of the disease at the onset, the ages of the patients concerned and the number of cells in the spinal fluid of the patients were about the same for the four groups of patients who received serum and who recovered with no paralysis or with varying degrees of residual paralysis.

The degree of residual paralysis that resulted was in direct proportion to the duration of the disease before the administration of the serum. Thus, among those patients who recovered with severe residual paralysis, the average duration of the disease before serum was administered was 4.3 days; among those who recovered and had moderate residual paralysis, the average duration of the disease before serum was administered was 4.7 days; among those who recovered and had slight residual paralysis the period was 3.5 days, and among those who did not have residual paralysis it was 2.3 days.

The much lower mortality (4.5 per cent) and much lower incidence of severe residual paralysis (3.3 per cent) in the group to whose members a serum had been administered in comparison with the mortality (19.8 per cent) and incidence of severe residual paralysis (34.4 per cent) in the group of controls seem directly attributable to the action of the antistreptococcic serum.

Favorable results were consistently obtained each year among the different groups of patients treated and with each of the different lots of anti-serum used. Evidence of the beneficial action of the serum was not limited to the effect on mortality and on the final outcome as regards residual paralysis. Beneficial action was noted at the bedside among nearly all patients to whom serum had been administered early, especially in the treatment of those patients who were in the pre-paralytic stage, and in many instances even after paralysis had begun to afflict some patients.

Restless, nervous children often fell asleep soon after receiving the first injection of serum. This was true alike of patients for whom spinal puncture was or was not made at the time of the injection of serum. Headache and pain in the involved extremity or part often were lessened or relieved. The temperature, especially among patients in the preparalytic stages, rapidly decreased to normal, usually after an initial transient elevation.

Progressive paralysis often was seemingly arrested. Restoration of muscular function was apparently more rapid among patients who received serum than among those who did not receive the serum. These favorable results, obtained since 1928, are in strict accord with those previously reported.^{6,7,13,14}

RECENT PROGRESS IN OTOTOLOGY*

H. NEWHART, M.D.

Minneapolis, Minnesota

PROGRESS in otology in past decades compared with other medical specialties has been embarrassingly slow, largely because of the inaccessibility of the ear and the crudeness of available methods employed in research and clinical practice.

Recently the application of electro-acoustic principles, radical improvements in surgical technic, revolutionary discoveries in chemotherapeutics and the recognition of overlooked factors which produce ear pathology have greatly increased our knowledge of the causes, prevention, treatment and alleviation of diseases of the ear.

Much of this newly acquired knowledge has been widely disseminated, sometimes in a sensational but impressive manner, by popular health talks, radio broadcasts and articles in the press. As a result, the intelligent layman not infrequently seems better informed regarding otological progress than the busy family physician. New responsibilities have thus been imposed on the medical profession in that the public today demands of the otologist and the general practitioner better service in the care of ear diseases than has been given in the past.

Therefore it seems appropriate for our better orientation to briefly indicate some of the recent advances in this field.

The development of the audiometer marked the beginning of a new era in otology. Its extensive use as an instrument for accurately measuring hearing acuity has made valuable research possible and revealed many important facts.

It early proved the inadequacy of our older methods for the detection of slight but significant hearing defects, the first requirement for solving the problem of faulty hearing.

It has disclosed a surprisingly large number of persons who have a handicapping or a potentially handicapping hearing loss, often unrecognized and neglected. The number in the United States is believed to be at least 10 million.

It has proved that among school children¹⁰ hearing deficiencies, frequently so slight as to be overlooked, cause repetition of grades, speech de-

fects, inferiority complexes and behavior problems which interfere with the development of a personality which will insure the individual's economic and social security. Recognition of this fact has resulted in recent legislation in several states making mandatory the periodic testing of the hearing of all school children by the audiometer¹¹ as the most effective means of conserving the hearing.

The chief obstacle to the more general adoption of this procedure has been the high cost of equipment. Very recently simple, reliable audiometers¹² especially designed for expeditiously and accurately testing large groups for school and industrial purposes have been released at a price so low that small communities with limited budgets can well afford to own them.

The audiometer has been found indispensable by otologists and is being rapidly adopted by general practitioners, school, public health and industrial physicians. In forensic work it has been found to be invaluable. Many physicians now use it in the periodic health examinations of their private patients.

The Council on Physical Therapy of the American Medical Association³ is rendering valuable service by formulating minimum specifications for reliable, standardized audiometers which can be sold at a moderate cost, thus safeguarding the purchaser against obtaining an inferior instrument.

Several million hearing tests with the audiometer have emphasized certain facts with which every physician should be familiar:

1. Accuracy in applying any hearing test is impossible in the presence of masking or distracting noise; and in making the test, the better hearing ear must be excluded. These simple but fundamental rules are too often ignored.

2. Handicapping hearing deficiencies appearing in adult life are very frequently the result of inflammatory processes in the ears in childhood.

3. Many individuals sustain a material hearing deficiency long before they themselves are conscious of their loss. This fact emphasizes the great importance of periodically testing the hear-

*Read at the annual meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 18, 1939.

ing at all ages by scientifically approved methods.

It is to be noted that today many more causes of hearing impairment are known than in the recent past. We mention the following:

Otologists in increasing numbers have accepted the teachings of Wittmaack,¹⁹ first published twenty years ago after extensive research. He showed that many inflammatory ear diseases and their complications have their origin in non-infectious, irritative reactions of the middle ear mucosa, caused by the entrance of non-infectious amniotic fluid and other maternal discharges. These are aspirated and forced through the tubes into the middle ear by the infant at the time of delivery. Such irritation causes abnormal development of the middle ear mucosa, whereby normal pneumatization of the mastoid is prevented and the capacity of the middle ear to resist infection is lessened.

Taylor^{16,17} has shown that the administration of quinine to expedite labor and the use of salicylates and arsenicals may cause deafness in the child. Evidence confirming Taylor's belief has been published by Mosher,⁹ who found that after the administration of quinine, salicylate of soda and mapharsen to guinea pigs, destructive hemorrhages were found in the cochlea of the fetus. Other investigators have found quinine and other drugs in the brain and cerebro-spinal fluid of infants whose mothers had been given these substances.

An important cause of hearing impairment among children has been reported recently in several papers by Crowe² and his associates. This is the presence of partially obstructing lymphoid tissue in and about the pharyngeal ends of the eustachian tubes. Its presence can be demonstrated by the nasopharyngoscope. The characteristics of this condition are early retraction of Shrapnell's membrane, hearing impairment first appearing in the upper frequencies of 4096 d.v., 8192 d.v., and higher, detectable only with the pitch range audiometer. Not until the hearing impairment has become more noticeable do the lower tones become materially reduced. This is contrary to our former teaching and is an outstanding contribution to our knowledge. Inflation proves unsatisfactory even after surgical removal of the adenoids. Brilliant results follow treatment of selected cases by irradiation with radium or the x-ray, a treatment to be safely

and effectively administered only by those especially skilled in radiology.

The above facts merit the serious consideration of all practitioners, but especially the obstetrician and the pediatrician.

From a scientific viewpoint, old age should not be considered a specific cause of severe hearing impairment. Physiologically there is a slow, gradual, measurable diminution of acuity for the higher frequencies with advancing years. This is not sufficient to produce a handicapping defect for hearing speech. Other factors have been operative during the life of the individual.

The treatment of middle ear infections and their complications caused by streptococci of the beta-hemolytic type and other susceptible organisms has been revolutionized by the use of sulfanilamide^{6,15} and related drugs. The reduction of the high mortality in cases of otitic streptococcus meningitis when this treatment is combined with adequate surgery is dramatic.

No other drug has received so much attention in medical literature. It would be idle repetition to discuss this subject further than to offer a few remarks based on recent observation and experience. Disappointment from its use may come from several causes. One is failure to observe closely the carefully prepared instructions of the manufacturers.

In acute middle ear infections early identification of the invading organism is important. When clinical symptoms point to a severe streptococcus infection, one often cannot afford to wait for the bacteriologist's report before beginning drug therapy. Failure may result from neglect to use the drug until after a complication has developed, from inadequate, uncontrolled dosage, or from its too early discontinuance.

What is most to be feared after a mastoid involvement has been clinically diagnosed is a false sense of security assumed because of a subsidence of symptoms. It is believed on competent authority that these drugs do not possess the same bacteriostatic power to overcome microorganisms when confined in collections of pus in closed or partly closed cavities such as exist in a confluent mastoiditis, an epidural abscess, brain abscess, or an abscessed lateral sinus thrombosis, as they exercise in tissues having a freely circulating blood supply.

Cases of this type are encountered in which,

after several weeks of latency, there appears abruptly a serious endocranial complication.

One can avoid such occurrences only by exercising extreme vigilance. So long as there is any purulent discharge from the middle ear, even though it be sterile, and so long as the hearing does not return to normal or nearly normal, or the tympanic membrane remains pale, lusterless and thickened, the patient should be kept under careful scrutiny and be checked at frequent intervals by roentgenographs of the mastoid, and examinations of the blood, and when indicated, of the cerebrospinal fluid. Evidence of progressive bone destruction, meningeal or labyrinthine irritation, facial paresis or a complete loss of hearing demand immediate, thorough, exploratory surgery.

There have lately been decided advances in the surgery of the temporal bone tending toward earlier and more thorough operative intervention. The term "simple mastoidectomy" is fast being supplanted by "complete mastoidectomy," more accurately to describe what should be done in the attempt to effect a cure in destructive supuration of the mastoid body. This means the thorough removal of all accessible diseased bone and the provision of adequate drainage from remote parts, as the tip, peri-labyrinthine, petrous and zygomatic cells, and exposure of the dura and lateral sinus whenever necessary to explain the symptoms.

The classic radical mastoid operation is less frequently performed than formerly, especially in cases in which the more conservative, modified radical operation, with preservation of the ossicular chain and the tympanic membrane, promises equally good surgical results and a better prospect of improving the hearing.

The endaural as distinguished from the post-auricular approach to the attic, middle ear, labyrinth and mastoid body is growing in favor among otologists, since it affords greater accessibility.

The most revolutionary advance in otologic surgery has been the long awaited, successful, one-stage fenestration operation of the bony labyrinth to improve the hearing in otosclerosis. This has lately been attained after persistent effort by Lempert.⁸ He recently reported seventy-two such operations, forty-four of which gave brilliant results in improved hearing, surpassing

the reported results of the few other operators in this field. The object of the procedure is to secure by a plastic operation a permanent fistula in the external bony semicircular canal, covered by a thin vibrating membrane obtained by transplanting a part of the drumhead. By thus again mobilizing the perilymph, the hindrance to sound perception by air conduction caused by fixation of the stapes is overcome.

The operation requires much time and great skill in plastic surgery in operating in an extremely small space. This can be acquired only by long study and highly specialized training.

It should be undertaken only on persons who still have good hearing by bone conduction, a large auricular canal and a normal tympanic membrane as established by a thorough otological examination. These requirements definitely restrict its application to relatively few of the thousands of otosclerotics who would make every sacrifice to recover useful hearing. This should be made known to those whose hopes have been raised to a high level by sensational newspaper reports regarding this operation.

Notable progress in ameliorating the condition of the aurally handicapped has resulted from recent improvements in the design and performance of electrical hearing aids. Many new features, developed in rapid succession by competing manufacturers, have confused the physician and sadly perplexed the prospective purchaser. In his helplessness against the high pressure salesmanship of certain vendors of hearing aids the patient confidently looks to his physician for help in selecting the hearing device which will best meet his requirements.

This important service can be rendered most satisfactorily after a careful otological examination, including audiometric tests for both bone and air conduction. With the information thus obtained one can specify whether a carbon type hearing aid will prove satisfactory or the patient will need one of the recently developed, compact, wearable vacuum tube types, which afford greater amplification and greater fidelity; also whether a bone conduction or an air conduction receiver is indicated.

The patient with a severe hearing loss showing great differences of acuity at various frequencies presents a difficult problem. Since different instruments possess definite but subtle differences

in their performance characteristics, capable of modification within certain limitations by selective amplification, the prospective purchaser should have the privilege of trying out the instruments of several reliable makers by the intelligibility test.^{4,5,7,14} Such comparative tests must be made under identical conditions by one who is not financially interested in the sale of any hearing aid, preferably a physician familiar with this simple procedure.

The Council on Physical Therapy of the American Medical Association,³ after thorough investigation, has pronounced the hearing devices of several manufacturers "acceptable" according to minimum standards of construction, performance and distribution set up by its Committee on Audiometers and Hearing Aids. Such accepted instruments are naturally recommended in preference to instruments of uncertain background.

The development of the wearable miniature vacuum tube type of hearing aid is a very recent accomplishment. For many whose hearing loss is extreme it often gives great satisfaction when the carbon type fails. Its advantages are the possibility of greater amplification without distortion. Its disadvantages are that it is more vulnerable and that when it suddenly fails to operate, it must be sent to the maker for repairs. The carbon type usually gives warning of impending trouble and can be reconditioned promptly by the nearby distributor. Vacuum tube aids at present have larger battery consumption than the carbon type.

The newer hearing aids have a far wider field of application than their predecessors. Persons with a moderate hearing loss who could not tolerate the adventitious noises of the old carbon transmitter available a few years ago can use a modern hearing aid with great comfort.^{1,18}

Young children whose hearing loss prevents them from acquiring normal speech, by using these devices in the home and schoolroom can acquire speech normally and can receive their education in the local schools.^{10,13}

It is a serious mistake to advise a person with a progressive hearing loss to postpone the purchase of a hearing aid as long as possible. By so doing he greatly increases his difficulties in becoming accustomed to one. Everyone who has a handicapping hearing impairment should be advised to begin early to perfect himself in the art of speech reading to further supplement his

hearing deficiency and enable him to keep his contacts in order to preserve his economic and social security. The hard of hearing person should be emphatically told that the purchase of a hearing aid is not the final solution of his hearing problem, but that he should do everything in his power, under the best medical guidance, to preserve his residual hearing by removal of all detectable causes which might produce further loss.

Conclusions

1. A better knowledge of fundamental otological facts affords a larger opportunity for the otologist, pediatricist and general practitioner to render more effective service.

2. Effective reduction of the high incidence of hearing deficiencies can be accomplished by the general adoption of the routine, periodic hearing test by scientifically approved methods, especially among school children, and continued as a part of the periodic health examination at all ages.

3. Improved hearing aids now available have a wider field of application than in the recent past. In prescribing or selecting them to best meet the specific requirements of each individual, the otologist or interested physician can render valuable help in protecting his aurally handicapped patients from obtaining an unsuitable or inferior device.

4. In selected cases, fistulization of the labyrinth in the hands of qualified operators promises the restoration of useful hearing for a large number of otosclerotics. Many who are not suitable subjects for the operation can successfully supplement their handicap by a modern hearing aid and lip-reading.

MANAGEMENT OF POSTOPERATIVE INTESTINAL OBSTRUCTION COMPLICATED BY HEMORRHAGE ON THE BASIS OF PROTHROMBIN DEFICIENCY*

CLAUDE F. DIXON, M.D. and ROBERT O. GREGG, M.D.

Rochester, Minnesota

PRESENTATION of this case is being made for three reasons: (1) the early age at which malignant change was found in a polyp of the colon, (2) the success of conservative treatment

since the patient was three months of age. The loss of blood was slight and at times there was freedom from bleeding for as long as two years. In the six months before coming to the clinic the bleeding had become more frequent and severe than formerly and the pa-

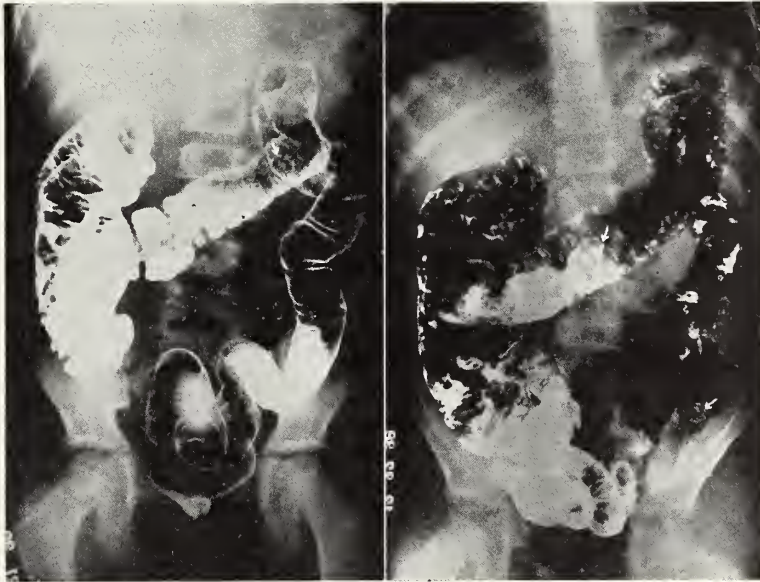

Fig. 1. Evidence of a polyp near the splenic flexure is indicated in the film on the left; evidence of a large polyp in the transverse colon and a polyp in the sigmoid is indicated in the film on the right.

of intestinal obstruction and (3) the occurrence of bleeding and a deficiency of prothrombin in prolonged intestinal obstruction.

A boy, seven years of age, of Irish parentage, was first seen at The Mayo Clinic on December 19, 1938. Rectal bleeding had been observed intermittently ever

since the patient was three months of age. The loss of blood was slight and at times there was freedom from bleeding for as long as two years. In the six months before coming to the clinic the bleeding had become more frequent and severe than formerly and the pa-

tient often passed a cupful of blood a few minutes after a normal stool. His health and development were excellent except that there was pronation of his feet. He weighed 67 pounds. There was no history of malignancy in his family. The examination revealed 14.0 gm. of hemoglobin per 100 c.c. of blood, and no abnormality of either the erythrocytes or the leukocytes was present. The findings on urinalysis were within normal limits and the results of flocculation test of the

*From the Division of Surgery, Mayo Clinic (Dixon) and The Mayo Foundation (Gregg), Rochester, Minnesota.

blood and roentgenologic investigation of the thorax were negative.

A proctoscopic examination revealed three small rectal polyps and roentgenologic investigation of the colon was advised. The roentgenologist employed the

Fig. 2. Segment of colon opened to show the polyps.

and the left ureter. A Witzel type of enterostomy was established at a site about 15 to 20 inches proximal to the cecum.

The pathologists reported that the specimen was composed of 28 cm. of transverse and descending colon. Some of the acini in a polyp 4 cm. in diameter in the transverse colon showed early carcinomatous change grade 1. The two polyps (0.5 cm. and 1 cm.) in the descending colon were adenomatous. If the gross appearance of the specimens is of any interest, this is shown in Figure 2. Figure 3 depicts the area of early carcinomatous change and also one of the adjacent adenomatous polyps for comparison. In one field in the region of malignant change, under high power, thirteen mitotic figures were counted.

This patient's immediate postoperative course was satisfactory, with the exception of a questionable re-

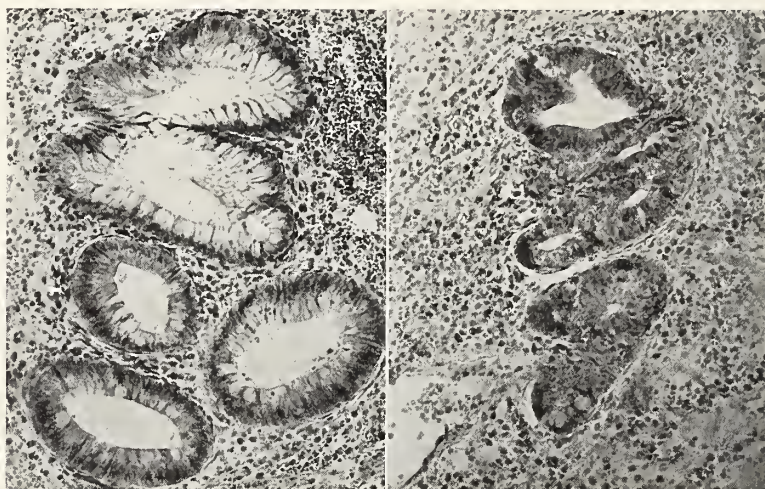

Fig. 3. Malignant change. The acini on the left show simple hypertrophy, the cells contain much mucus and an occasional rare mitotic figure is seen. The acini on the right show absence of mucus, irregular arrangement of cells and numerous mitotic figures.

double contrast method and reported, "A polyp 1.5 by 1.5 cm. in the descending colon just below the crest of the ilium; another smaller polyp in transverse colon adjacent to the splenic flexure, and a third large polyp in the transverse colon just to the right of midline" (Fig. 1).

An operation was advised. After thorough preparation this was performed by one of us (Dixon) on January 10, 1939. The three polyps were readily located. Careful palpation of the ascending colon and right half of the transverse colon showed no abnormality. Resection of the transverse and descending colon was carried out, removing the colon down to the first part of the sigmoid. The ends of the colon were inverted and a side-to-side anastomosis was established between the hepatic flexure and first portion of the sigmoid. The operation was carried out in one stage because the application of clamps for closure of a colostomy would have been extremely difficult and would have been attended by the hazard of injury to the retroperitoneal portion of the duodenum

action from a transfusion on the fourth and sixth postoperative days. However, on the sixth day signs of high intestinal obstruction developed, the output by nasal suction rapidly rising to 3450 c.c. on the ninth day (Fig. 4). Because of fever which had persisted since operation, abdominal tenderness and the absence of isolated, crampy pain, conservative treatment of the intestinal obstruction was instituted. Distention persisted in spite of transduodenal drainage with the Sawyer tube, and a Miller-Abbott type of tube was passed on the thirteenth day. When this entered the jejunum on the fifteenth day there was almost immediate relief of obstruction, as evidenced by diminished output from suction and profuse drainage from the enterostomy tube (Fig. 4). The nasal tube was removed and the diet was gradually increased. Obstruction recurred. This was at first only partial but gradually increased and became nearly complete by the twenty-fifth postoperative day. On the evening of that day he began to pass blood per rectum and by 4 o'clock the next morning a total of 800 c.c. had been passed. The Quick prothrombin

time measured two minutes and twenty-one seconds. A transfusion of 500 c.c. of citrated blood was given in divided amounts.

The abdomen was reopened. A large edematous dilated loop of small intestine was encountered. Because

pain. Since the enterostomy had brought about release of the obstruction at the proximal end of the upper loop, it was possible to introduce vitamin K by nasal tube into the duodenum. Accordingly, 2 c.c. of Klotogen and 6 gm. of bile salts were given by nasal tube;

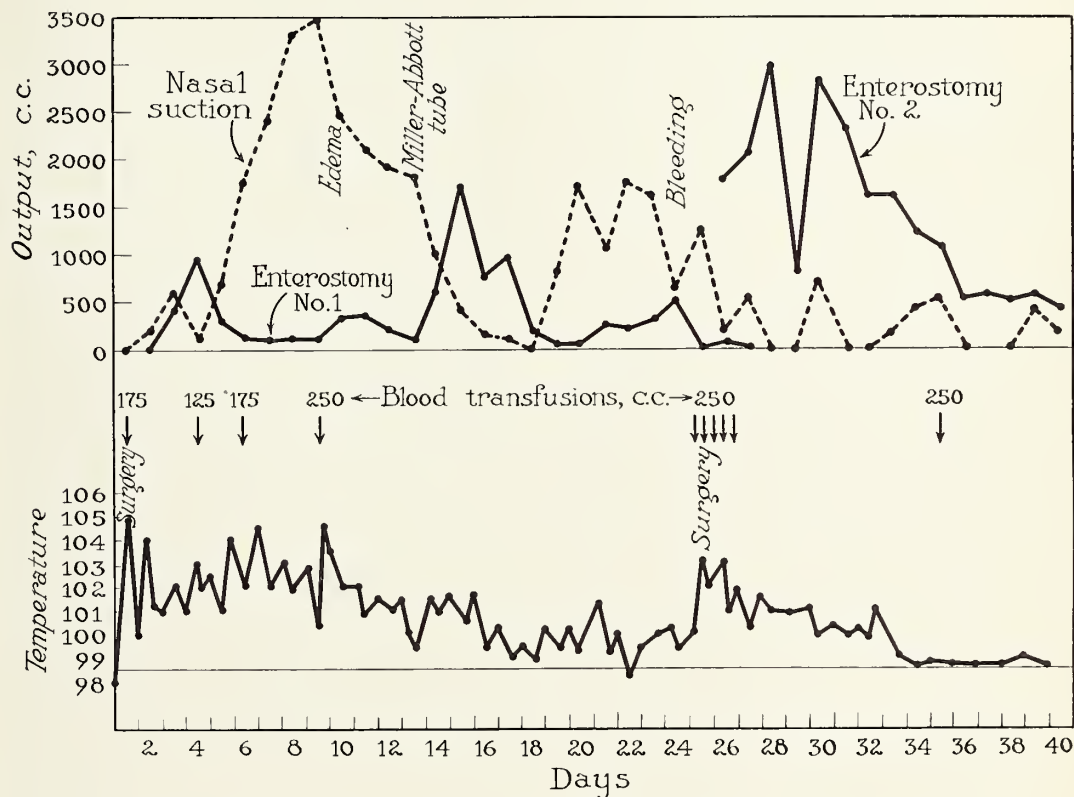

Fig. 4. Postoperative course; relation of febrile reaction to output by nasal suction and enterostomy tubes.

of the critical condition of the patient an exhaustive exploratory procedure was not carried out. An enteric stoma of the Witzel type was established in the dilated loop of bowel. Profuse rectal bleeding continued for eighteen hours following enterostomy, and 750 c.c. more of citrated blood was given by transfusion. The obstruction in the upper end of the dilated loop of bowel was relieved promptly by enterostomy, and this was followed ten days later by release of the obstruction at the lower end of the loop. That the new enterostomy was the means of relieving the obstruction at the upper end of the loop is evident from the fact that material flowed out of the new opening promptly and the output by nasal suction was diminished; release of the lower obstruction ten days later (Fig. 4) was shown by cessation of drainage from the enterostomy tube and by the establishment of a normal fecal content in the bowel.

On the day of operation (after 750 c.c. of blood had been given), the prothrombin time (Quick) had fallen to forty-four seconds. Capsules of vitamin K were given that day through the original enterostomy tube but had to be discontinued because of severe cramping

500 c.c. of citrated blood was also given in the twenty-four hours following operation. By the end of that period all bleeding had ceased, the Quick prothrombin time (Fig. 5) had fallen to twenty-four seconds and the Smith quantitative test revealed 51 per cent normal concentration of prothrombin in the blood. Two cubic centimeters of Klotogen with bile salts was administered on each of the successive four days. At that time, the tube was removed but further therapy with vitamin K was carried out by giving it in capsule form for the next six days. This maintained the Quick prothrombin time between nineteen and twenty-one seconds.

After establishment of the second enteric stoma it was observed that material given by mouth appeared in the drainage from the enterostomy in one hour. To utilize all possible digestive and absorptive surface, the drainage from the proximal enterostomy tube was incubated for four hours and then was introduced into the terminal portion of the ileum through the lower or original enterostomy tube.

During the period of obstruction this patient was also given 25 mg. of betaxin representing 8300 units of vitamin B, and 4 c.c. of cevitic acid (400 mg.) by vein.

On the tenth postoperative day, edema of the eyes, legs and scrotum developed, but prompt relief followed the administration of 110 grains (7.15 gm.) of ammonium chloride by enterostomy tube in three days.

At the last report on April 27, 1939, the patient

undergo malignant transformation. Single polyps display a definite inclination to become malignant. In 5 per cent of the cases of single polyps reviewed by Brust, definite carcinoma developed in the brief period of five years. Unmistakable evidence of early malignant transformation was found in a group of glands in the large polyp in the transverse colon of the patient whose history has just been given in detail.

The problem of postoperative intestinal obstruction is one which taxes the judgment of the surgeon to the utmost. Wangenstein and associates, in a recent article, have reiterated the indications and contraindications for the treatment of intestinal obstruction by suction. If one suspects that there is interference with the blood supply of any loop, immediate exploration is the outstanding indication regardless of the state of the patient. In the present case, the onset of distention was gradual, pain was not severe, there were no definite localizing signs, and because the obstruction was high in the small intestine, conservative treatment was employed. In this instance, nearly complete obstruction persisted from the sixth to the thirteenth postoperative days, and from the nineteenth to the twenty-fifth postoperative days. Regardless of the prolonged obstruction, the urea, chlorides and carbon dioxide combining power of the blood were maintained within nearly normal limits.

We corrected the tendency toward alkalosis and edema which occurred on the ninth day by the administration of ammonium chloride through the enterostomy tube. Deficiency in vitamins B₁ and C was prevented by administration of these substances intravenously. It has been shown through the work of Brinkhous, Smith and Warner, Quick, Dam, Snell, Butt and Osterberg that the presence of bile and a "Koagulation" factor in the intestinal tract are necessary for the formation of prothrombin. It is probable that prolonged starvation and loss of bile from the upper portion of the intestinal tract resulted in the absence of vitamin K from the intestinal tract and subsequent prothrombin deficiency in the case reported. We believe also that the multiple transfusions of fresh blood introduced sufficient prothrombin to tide the patient over temporarily until the enterostomy could be performed and surface for absorption could be made available.

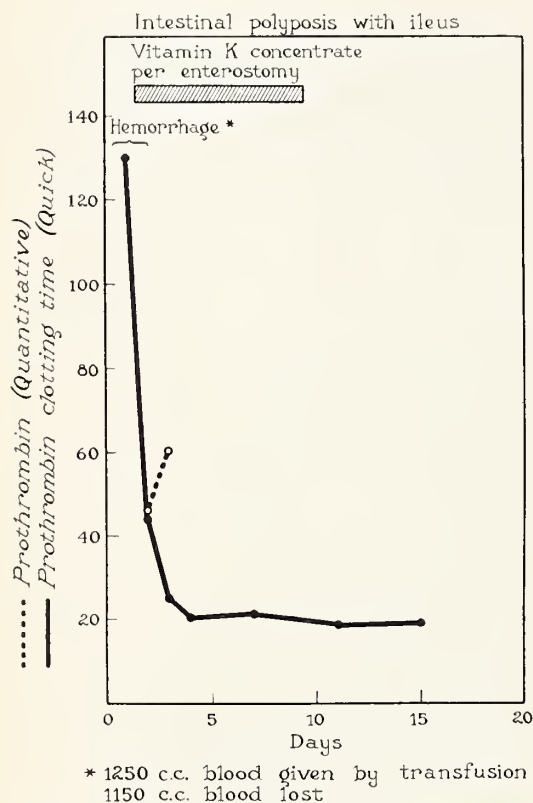

Fig. 5. Prompt return of the prothrombin time (Quick) and quantitative prothrombin to nearly normal values after transfusion and administration of vitamin K concentrate; after the first day the vitamin K was given by nasal tube rather than by enterostomy tube.

weighed 76 pounds, 9 pounds more than when he first came under our care, and he was attending school regularly and leading a normal life. He is to return for fulguration of the polyps in the rectum. Because of the possibility of development of further polyps in the colon and the advantage of early recognition of such lesions, the condition of the intestinal tract should be observed at frequent intervals in the future.

Comment

From the history of rectal bleeding, rectal polyps apparently had been present since the patient was about three months of age. Doehring, Lockhart-Mummery,^{5,6} Miller and Sweet, Wesson and Bargen, Mayo and Butsch, Brust and Rankin and co-workers have frequently emphasized that there is a tendency for rectal and colonic polyps, particularly of the diffuse type, to

Summary

A case of a boy, aged seven years, who had multiple polyps of the colon with malignant change in one of the lesions has been presented. The patient's postoperative course was complicated by intestinal obstruction and ultimately by rectal bleeding which ensued from prothrombin deficiency. With conservative treatment the chemical constitution of the patient's blood was maintained within nearly normal limits until the twenty-fifth postoperative day, in spite of persistent intestinal obstruction. An enterostomy of the Witzel type was sufficient to relieve the obstruction permanently. The rectal bleeding which developed on the twenty-fifth postoperative day on a basis of prothrombin deficiency was treated successfully by multiple transfusions of fresh blood and the administration of vitamin K and bile salts.

ALLERGY IN GENERAL PRACTICE*

H. J. ROEMER, M.D.

Winona, Minnesota

SINCE various estimates^{1,2} indicate that from 7 to 10 per cent of the total population exhibits some manifestation of the allergic state, the general practitioner of medicine must of necessity give an increasing amount of attention to this phase of medical practice. Discovery of the offending allergens, their elimination, or the use of specific desensitization can be accomplished by following certain practical methods, the cost of which is not excessive and the results good if one has the time and patience to investigate each case to the limits of its possibilities. The following discussion will include those methods which have been found practicable in discovering the causative agent or agents together with brief case reports to illustrate certain principles of investigation.

The factor of hypersensitivity must be considered in many illnesses. We well know its etiologic relationship in hay fever, allergic coryza, bronchial asthma, urticaria, angioneurotic edema

and atopic eczema. There are definite proved instances of gastro-intestinal allergy, allergic migraine and bronchitis. Its importance in such conditions as "spastic colon," "mucous colitis," acne and other more obscure disorders is still largely a matter of romantic speculation.

Clinical Diagnosis

The symptoms in the average case are typical and easily recognized. The more obscure type of case needs to be more critically evaluated. It certainly is not rational to conclude that because a given patient's symptoms are obscure they must be "allergic." In a given doubtful case one or more of the following criteria should be present in order to merit an allergic investigation:

1. Presenting symptoms or objective findings which definitely suggest an allergic state and which can be explained on the basis of smooth muscle spasm or by increased capillary permeability.

*From the Winona Clinic. Read at the annual meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 18, 1939.

2. The occurrence of one or several other manifestations of allergy.
3. A positive family history.
4. The presence of a blood eosinophilia.

History

The value of a careful and detailed history could hardly be overstated. It is equal in value to the more spectacular skin tests. It will frequently indicate contacts and suggest relationships which, when investigated, lead the way to the agent or agents responsible for the patient's symptoms. This is the place where one can do his good work in an obscure case of bronchial asthma. It costs nothing except time. One to several hours of questioning, recording, and study of significant data are required. The history alone, if complete and detailed, coupled with elimination of suspected offenders, will solve many a problem without the use of extensive cutaneous testing. The following case will illustrate this point:

Case 1.—J. M., aged twenty-one, was seen on August 22 with a severe attack of bronchial asthma which required adrenalin for relief. He complained of wheezing and difficulty in breathing, which had recurred with increasing severity during the past month. He had had no previous attacks. Because of the date of onset of symptoms, pollen sensitivity was, of course, suspected. On further questioning it was found that he was employed in the tablet department of a local patent medicine concern for the past six months and that during the past week he had assisted in the manufacture of a tablet containing licorice root. No other changes in his environment could be elicited. A sample of licorice root was obtained and when he inhaled this a typical attack of asthma was produced. A shift to another department was followed by complete relief of symptoms.

The important part of the history resolves itself into the study of two things, closely related: (1) the individual attacks; and (2) a study of the environment and particularly the changes in environment and whether or not these changes are associated with corresponding changes in symptoms.

The Attacks.—Räckemann³ has stressed the importance of a careful study of the individual attacks, noting the exact dates of onset and cessation of symptoms beginning with the very first attack and following through each subsequent one, noting all associated changes in environment and possible causative factors. Sym-

toms that have a definite seasonal incidence corresponding to dates during which certain pollens are prevalent are obviously due to this factor. Hay fever and asthma occurring only in April are probably from trees, in May or June from grasses, in August and September from ragweed. In the winter months they are likely to be due to dusts, feathers, mattress or the like. Urticaria in June or July is probably from some seasonal food. The time of day in which most attacks begin is important. The person who is entirely free from asthma except at night or when he lies down in the afternoon is probably sensitive to some part of his bedding (feather pillow, mattress dust, wool blankets, et cetera). The person who has headaches after Sunday dinner and at no other time probably is sensitive to some favorite dish which he seldom has at any other time. The individual who has abdominal pain and a loose stool after breakfast frequently, and rarely at other times, probably has an intolerance for eggs, coffee or some other breakfast food.

The Environment.—Inquiry into the patient's occupation, its hazards, and especially the dusts or fumes connected with it may lead to the discovery of the cause of trouble. The residence is important. Farm houses have dusts from animals, hay, grain, fertilizers and insecticides which may be quite different from the dusts of cities. Changes in residence, occupation or place of work and the effect on symptoms or the lack of effect, often furnish an important lead.

Case 2.—The following case is that of a young woman, aged 25, a beauty parlor operator, who complained of watering and itching of her eyes, swelling about the eyes, stuffy, "runny" nose and frequent sneezing intermittently for two years. Symptoms occurred at home as well as at work but were more severe while at work and most marked when cutting and combing hair. She had worked at Marshfield for four months during this period and while in Marshfield she was free of symptoms. A study of the various types of preparations used in her work showed that she had used at home a wave set containing gum karaya which had not been used while at Marshfield. A sample of gum karaya powder when inhaled caused a typical severe "hay fever." Elimination of this wave set was followed by complete cessation of symptoms.

Hospital admissions are of great value. Not only does the patient escape from his home but he lands in an environment in which experience has shown that almost all the extrinsic cases of

asthma become symptom-free within a period of five days. When a patient has always lived at home with no change of any kind a study of the history is difficult chiefly because of the absence of history. In such an instance he can be moved away from home and the effect of the change observed.

General Physical and Laboratory Study

Complete physical and laboratory studies are of course, essential. The appearance of the mucous membrane of the nose in allergic coryza is frequently very characteristic: this appears pale, edematous and some thin watery secretion can often be seen. A smear of the nasal secretion shows a predominance (ten per cent or more) of eosinophiles. Leukopenic index studies are of doubtful value in the study of any allergy.

Cutaneous Tests

The elaborate set-ups for skin testing utilized in the large allergy clinics are, of course, financially impracticable in the average office. However, one should have, in addition to pollen extracts, an assortment of at least 100 test materials including all the known "common offenders" and one should be prepared to do both scratch and intradermal testing. Scratch tests are always used in testing for pollens and also for inhalants and foods in highly sensitive individuals. In testing infants and small children the pressure puncture method as advocated by Stoesser⁴ is the method of choice. Intradermal testing is used in all other cases and will frequently show sensitivities not demonstrated by other methods.

Elimination and Trial Diets

In a suspected food allergy, when skin tests are negative or when symptoms are not controlled by diets which exclude foods to which skin reactions have occurred, "elimination" or "trial" diets as advocated by Rowe⁵ and Vaughan⁶ are indicated and are of decided value in localizing these offenders.

Modified Trial Diet

The following initial diet, which consists of foods least likely to cause distress, may be used for a period of five days:

Soup: Lamb or mutton broth, containing rice if desired.

Meat: Lamb or mutton, roasted or served in the form of stew or chops; lamb patties or hash; cold

sliced lamb; casserole of lamb and rice; lamb and rice croquettes.

Cereal: Rice krispies, puffed rice, rice flakes, rice flour, boiled rice; pear juice or butter may be added.

Fruit: Pears, preferably baked with granulated sugar, pear juice, canned pears, stewed pears, or fresh pears without skin and seeds.

Sugar: Granulated or powdered only.

Fat: Butter or lamb fat only.

Seasoning: Salt only.

Beverage: Clear tea or water.

Suggestion.—For breakfast you may eat a lamb chop with puffed rice, rice flakes or steamed rice with butter or sugar, or some of the syrup from a can of pears. Cooked rice may be made into little cakes, and fried lamb, again with rice and canned pears. No coffee, sodas, fountain drinks or candy should be taken, and even chewing gum should be avoided.

After the fifth day add new foods once every fourth to seventh day in the following order: beef, potato, gelatin, carrots, turnips, asparagus, string beans, arrowroot cookies, rye crisp, thin toast, and oatmeal.

Environmental Control

This consists essentially in making the environment in which the patient lives and sleeps as completely dust-free as possible. All sources of inhalant allergens are eliminated. This procedure may be used for diagnosis and for treatment. Rowe⁵ gives the following instructions for the preparation of a dust-free room:

Instructions for the Preparation of a Dust-Free Room

1. Your room should contain only one bed, preferably an iron one. If there is more than one bed in the room, it, too, must be prepared as will be described.

2. All the furniture, rugs, curtains, and drapes must be taken from the room, the clothes closets emptied and the room cleaned as follows:

- a. Seal all the furnace pipes leading into the room. Clean the wallpaper. Scrub the woodwork and the floors in the room and closets. Wax the floors. Washable scatter rugs may be used.

- b. Scrub the bed. Scrub the springs. This must be done outside the cleaned room. If you use a box spring, it must be completely encased as will be described. Cover the mattress, pillows and box springs with dust-proof encasings (covers). The covers must be made of material which is not porous, is allergen-proof. These encasings must be sewed on or otherwise closed up so they are completely air-tight. This must be done outside the cleaned room.

Now set up the bed in the cleaned room, and on it place the cleaned or encased pillows and freshly washed

bedding. All bedding must be made of material which will stand frequent washing. No quilts or comforters should be used.

c. Wooden chairs which have been scrubbed may be used in this room. Rag rugs washed at least once a week may be used on the floor. Plain light curtains washed once a week may be used on the windows.

d. This room must be cleaned thoroughly once a week.

3. You must sleep in this room. All dressing and undressing must be done elsewhere in the house.

Articles of furniture which contain allergenic dusts should be removed from the house, especially from adjoining halls and rooms, if possible. Otherwise each article should be vacuum cleaned thoroughly every day at a time when the patient is away from the house. Following the vacuum cleaning the house should be aired thoroughly.

This is especially valuable in the control of so-called house dust sensitivity. House dust sensitivity is essentially a composite sensitivity. This substance originates primarily from deterioration of furniture stuffing and mattresses. It frequently can not be broken down into other more specific sensitivities and must be considered and treated as an entity.

Case 3.—R.D., a male, aged twenty-eight, gave a history of recurrent asthma since the age of eight, recurring during both summer and winter months and frequently disabling him for periods of from one to several days. Adrenalin was often required for relief. His symptoms were always worse during August and September. He stated that he usually felt well when he came home from work but his chest "tightened up" during the night and his wheezing was most marked on awakening in the morning. Scratch tests with the various pollens gave a marked positive reaction to ragweed. Intradermal testing showed a marked 4-plus reaction to house dust and a 3-plus to mattress excelsior. The remainder of the tests were negative. A program of "allergic cleanliness" was instituted in his bedroom and living room followed by relief of asthmatic symptoms and therefore this regime was continued. Pollen desensitization was begun the following year. He has had no recurrence of symptoms except for mild wheezing associated with upper respiratory infections on two occasions.

Case 4.—A boy, aged twelve, had had an asthma for three years recurring every August and duration several weeks. Symptoms were also severe during the winter months. Symptoms were worse when inside the

house, when playing with cats, and when a certain brand of fly spray was used in the house. Some of his attacks had come on while playing in the barn. His mother stated that his asthma was always worse on a rainy day and that he had a habit of sleeping on an old couch on the front porch on rainy afternoons. Physical examination, laboratory study and radiographs of his chest were essentially negative. A series of scratch tests were negative.

Intradermal testing gave the following positive reactions:

House dust++++
Cow dander+
Dog hair+
Chicken feathers+
Mattress+
Peanuts+
Tomato+
Corn+

The following therapy was advised: (1) Environmental control; (2) advised to dispose of the above-mentioned mattress and to stay away from all the farm buildings except the house; (3) desensitization against ragweed.

This regime was carried out and there has been no recurrence of symptoms.

Specific Desensitization

The value of this method in hay fever is well known. It may also be accomplished in other inhalant allergies. In the majority of cases of food allergy it has not proved successful.

Summary

Rational investigation and control of allergic disorders is by no means a difficult procedure and can readily be carried out in the average office without excessive cost to the practitioner.

Investigation should be continued until every allergic factor has been found and controlled.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF MEDICINE IN HENNEPIN COUNTY

BY A. S. HAMILTON, M.D.

(Continued from February issue)

Minneapolis Hospitals

(Continued)

REST HOSPITAL was established in 1894 at 2527 Second Avenue South, and was operated as a general hospital admitting both medical and surgical cases. Among those on the staff were Drs. J. W. Little, W. A. Jones, H. W. Jones, and J. W. Bell. It was so operated by trained nurses until 1931, at which time it was taken over by Drs. Arthur S. Hamilton and Hewitt B. Hannah for the care of nervous and mental cases exclusively.

The SWEDISH HOSPITAL was incorporated January 4, 1898, and opened for the reception of patients in the old Judge Cornell residence at 1419 Ninth Street South, with a capacity of twenty-five beds. The first year, 238 patients were cared for. The training school for nurses was opened in 1899, and in 1900 "The Swedish Hospital and Nurses' Institute," an auxiliary corporation, was formed which purchased ground and erected a new hospital at the corner of Tenth Avenue South and Eighth Street.

The first medical staff consisted of Drs. A. E. Anderson, O. A. Fliesburg, Alfred Lind, Joseph A. Prim, and C. J. Ringnell; but the following are included in a list from another source as those serving on the original staff: *Surgery*—Drs. C. J. Ringnell, A. Soderlind, U. G. Williams, C. M. Kistler; *Medicine*—Drs. C. J. Lind, S. P. Rees, J. M. Kistler, A. E. Anderson, Gilbert Seashore, B. Dearborn; *Eye and Ear*: Drs. H. McL. Morton and J. G. Ericson; *Nose and Throat*: Dr. E. H. Parker; *Diseases of Women and Children*: Drs. Alfred Lind, O. A. Olson, J. H. Rishmiller, A. E. Johnson, J. Frank Corbett.

The hospitals, medical societies and medical celebrities of the current century are too recent to include in the early history of Hennepin County Medicine. Nineteen hundred has been chosen as the fitting end of this volume. The events and personalities that have crowded upon each other in the space of a generation since the close of the century must have space for their dramatic chronicle in a later volume, for which, perhaps, the efficient secretaries of the present day are preparing more accurate and more accessible source-material, if not more picturesque.

The following is the list of officers of the Hennepin County Medical Society so far as I have been able to learn them. In most instances the names are taken from notices published in the papers at the time of the election, and a few are taken from directories, which have not been found a very satisfactory source:

1855—President, A. E. Ames
Vice President, C. L. Anderson
Secretary, Dr. Wheelock
1862—President, A. E. Ames
Secretary, R. H. Ward

1867—President, A. E. Ames
Secretary, N. B. Hill
1868—Presidents, A. E. Ames and N.
B. Hill
Secretary, N. B. Hill

1931—President, S. H. Baxter Vice President, Moses Barron Secy.-Treas., Erling W. Hansen	1935-1936—President, R. R. Cramer Vice President, J. H. Simons Secy.-Treas., O. J. Campbell
1931-1932—President, Moses Barron Vice President, J. C. Michael Secy.-Treas., Erling W. Hansen	

In the above list of presidents, names are lacking for 1876, 1882-1883, 1886-1887, and 1887-1888. To fill these vacancies we have the names of Dr. F. E. Towers and either Dr. Woodling or Dr. Salisbury, so that I am still lacking the names of at least two of the ex-presidents. The year 1902 marks the change in the election of president from the middle to the end of the year. On this account, Dr. J. W. Bell served as president all of the year 1903 and half of the year 1902.

Health Officers

The Minneapolis Board of Health was organized in 1867 upon the incorporation of the city. This first board, or Sanitary Committee as it was called, consisted of Drs. A. E. Ames, N. B. Hill and A. H. Lindley. The last named was designated as Health Officer.

Since 1889, this title was supplanted by that of Commissioner of Health according to the proceedings of the City Council.

In the Council proceedings of 1879-1880 the office of City Physician is first mentioned. Under an act of the legislature, passed April 21, 1891, the Board of Charities and Corrections was organized, which biennially appointed a city physician and delegated to him the duties of Superintendent of Hospitals.

In 1919, the Board of Charities and Corrections was superseded by the Board of Public Welfare by act of the legislature. But in 1913, a civil service commission was organized in Minneapolis which provided that all of the employees of the Board of Public Welfare, except the Commissioner of Health, be subject to suspension or dismissal only by the Civil Service Commission. The dual position of city physician and superintendent of hospitals was continuous then under civil service, until the organization of the Board of Public Welfare in 1919. According to the charter provision arising out of the act which established the Board of Public Welfare, the city physician must be a licensed practitioner of medicine in Minnesota. In case the superintendent of hospitals is not a duly licensed practitioner, a city physician must be appointed who qualifies as such.

Coroners

The following physicians have served as coroners in Hennepin County since 1869, at which time David Morgan is reported as being appointed county coroner: David Morgan, Charles Blecken, O. P. Chilstrom, P. Nelson, A. C. Fairbairn, R. J. Hill, Frank E. Towers, Wm. J. Byrnes, W. P. Spring, George E. Dennis, Henry S. Nelson, U. G. Williams, J. M. Kistler, and Gilbert Seashore (the latter having now served as coroner for twenty-eight years).

(To be continued in April issue.)

President's Letter

MAN follows the path of least resistance. It is very easy to ride along contentedly until a sudden jolt arouses us from our lethargy. It required several law suits involving large amounts to arouse sufficient interest on the part of organized medicine to study systematically disease caused by industry. Possibly these verdicts have been excessive and some of them unwarranted. But the fact remains that they were awarded.

The largest verdicts have been in cases involving dust. Eminent physicians, specialists of national repute, have testified against each other in many of these cases as to whether the individual had tuberculosis or silicosis or both as a result of dust.

Various other diseases, including lung diseases of different kinds, syphilis, kidney disease, dermatoses, and even appendicitis, have been declared by the courts to be compensable diseases.

This has resulted in intensified study on the part of organized medicine. The American Medical Association formed a new department in 1937 called the Council on Industrial Health. This Council held its second annual Congress on Industrial Health in Chicago last month, Northwestern Medical University formed a Department of Industrial Medicine in 1936, which is supported jointly by a group of industries and the University. This department held its third annual Symposium on Industrial Medicine in September. Other medical schools are following suit. At these meetings papers were presented by very able men on disabilities caused by such hazards as dust, welding, heat, and electricity, as well as various diseases which may be caused or aggravated by work in various lines of industry.

In Wisconsin the Industrial Commission is urging industry to institute periodic examinations of all employees. In all this organized labor seems to coöperate. The International Harvester Company has required an annual examination of every employee for many years and in addition a chest film every third year. This includes workers in their group of mines on the Mesaba Range. Many of the other mining companies are now doing the same.

At the second Annual Congress of Industrial Health last month, a paper was read by Terry C. Foster, U. S. Office of Education, Washington, D. C., on Rehabilitation in Relation to Medical Practice and Workman's Compensation Procedure which indicates the new trend of thought. The tendency in the past has been to care for a badly injured man, restore him to the best possible condition, testify for him before the compensation board, and then drop him. But this program is no longer considered sufficient. Means should be developed whereby the physician may be the advisor to some rehabilitation group which will train the crippled individual. If possible, he should be returned to his usual occupation. If that is impossible, he should be given training along some line of work that he can do so that he may become wholly or at least partly self-supporting. Then the physician, the rehabilitation group and the Compensation Board working together can more equitably estimate the disability.

A new committee has been formed in our State Association to study and investigate these problems, to learn what is being done elsewhere, and to make suggestions and advise procedure to be followed. It is called the committee on Industrial Hygiene and Occupational Disease. This is a large subject and a most important and timely one.

BERTRAM S. ADAMS, M.D., President
Minnesota State Medical Association.

MORTALITY TRENDS IN 1939

THE mortality experience of the Metropolitan Life Insurance Company, paralleling as it does that of the country as a whole, is each year most interesting. The report of this company in its bulletin for January, 1940, indicates the trend of national health in 1939, and also during the past decade.

The health of the country apparently continued during 1939 at a high level, although the mortality rate may prove to have been slightly higher

in the general population than the all-time low rate of 1938.

The marvelous advances in the feeding and care of infants in recent years have in large measure accounted for the great increase in life expectancy in our population. The continued decrease in mortality from the contagious diseases has further increased the life expectancy to the present high record of sixty-two years. While vaccination can be given some credit for the continuous reduction in diphtheria, other unknown factors account for the decrease in other contagious diseases.

Publicity campaigns probably should be given some credit for the continuous reduction in infant and maternal mortality. Certainly the concerted efforts directed to combat tuberculosis deserve the credit for halving the mortality from this disease in the past ten years and for cutting it to one-fifth of that in 1911.

One of the outstanding accomplishments in 1939 was the marked reduction (15 per cent) in the mortality rate from pneumonia in spite of an increase in mortality from influenza. It is safe to predict that the new dye therapy will show a marked further improvement in this regard unless the savings in lobar pneumonia are offset by an influenza epidemic.

It is yearly astonishing to learn that deaths from accidents of all kinds continue to decline. The high toll from automobile accidents each year is tremendous and impresses itself on our minds. Even automobile deaths in 1939, however, were slightly lower than in 1938 and the lowest since 1926, in spite of increased automobile traffic. The great saving in deaths from all accidents has been in industry, and has been so great that the number of fatal accidents has actually decreased in recent years.

The lowered birth rate and restriction of immigration in recent years and the increase in life expectancy have all resulted in a higher percentage of the population being in the latter decades of life. Thus the mortality from diseases incident to the later years of life—cancer, heart disease and diabetes—have naturally shown an increase in 1939 as well as in previous years.

The increase of 30 per cent in cancer mortality in the last ten years may not be actually as great when the improved methods of diagnosis of internal cancer are considered. This is a disease, however, which requires concentrated effort in order to attain earlier detection when cure is possible. Deaths due to coronary artery disease last year were nine times those so diagnosed ten years ago. Allowing for the possibility that the profession may be coronary-minded and may be over-diagnosing the disease, the actual increase in incidence of this disease and its appearance so frequently in the fourth and fifth decades is cause for alarm. It seems paradoxical that with the marked improvement in the treatment of diabetes the mortality has continued to increase in recent years with the exception of 1938, when there was a slight decline. Although treated diabetics live longer, the mortality rate for this disease is still increasing. Not only is the disease more often detected but the incidence of the disease has definitely been on the increase. This must be related to the high per capita sugar consumption in this country.

Of interest, too, is the drop of 20 per cent last year in the mortality attributed to alcoholism. The fact that the death rate was one-third of that ten years ago suggests that the American public is developing a little more sanity in its use of alcohol.

The improvement in the general health of the American people as reflected by the decrease in mortality is due to many factors. Practicing physicians should not forget the important part played by the sanitary engineer in providing clean water supply. Deaths from typhoid fever have been reduced to less than one per 100,000 population. Public health activities and a more health-minded public also account to some extent for the improvement.

CORONARY OCCLUSION AND THROMBOSIS

IN 1912, Herrick first called attention to the syndrome of coronary thrombosis. A full ten years elapsed before the diagnosis came to be commonly made.

The typical syndrome consists of the sudden onset of precordial pain or distress lasting several hours with a fall in blood pressure, pallor and cold perspiration and the development of an elevation of temperature, a leukocytosis and at

times a pericardial friction rub. Changes in the electro-cardiogram confirm this diagnosis.

Such a typical picture is not difficult to diagnose, but the atypical case may prove disconcerting. There may be vomiting and epigastric location of the pain, or the pain may not be severe and the blood pressure may not be low.

The interpretation of cardiac pain in terms of the pathologic process in the heart and particularly in the coronary vessels is important to every physician. The cause of angina pectoris is now recognized as being an anoxemia of the heart muscle. When this lasts a few minutes it is due to a temporary lack of sufficient oxygen for the needs of the heart muscle at that time and is generally due to an arteriosclerotic narrowing of one or more coronary vessels. Prolonged duration of the pain is likewise due to anoxemia of the heart muscle and the cause is usually a thrombosis or an occlusion in a coronary vessel.

The terms coronary thrombosis and coronary occlusion are commonly used interchangeably. That the two processes are not identical is clearly shown in a recent article by Blumgart, Schlesinger and Davis.* These authors selected all cases in which there was clinical or necropsy evidence of heart disease in a consecutive series of autopsies. The coronary vessels were injected with a colored radio opaque solution, x-rayed and then dissected. The simultaneous injection of colored material gave information as to regions supplied by right and left coronary arteries or both.

In brief, these authors showed that in the presence of coronary arteriosclerosis with narrowing of the vessels collateral circulation is established between the right and left coronary arteries where it is needed. Whether these connecting arteries are newly formed or are enlargement of already existing minute vessels known to be present normally is not known. One of the startling facts which they have proved is the existence of coronary occlusion in not only one but, at times, in two or three main coronary branches in many cases in which there was no clinical history of symptoms of coronary thrombosis or even angina pectoris. The previous development of collateral vessels is given as the explanation for the ab-

*Blumgart, Herman L., Schlesinger, Monroe J., and Davis, David: studies on the relation of the clinical manifestations of angina pectoris, coronary thrombosis and myocardial infarction to the pathological finding. *Am. Heart Jour.*, 19:1, (Jan.) 1940.

sence of symptoms. Just as startling is the absence of old infarcts in these cases and this absence is explained also by the presence of collateral vessels.

There is, then, a distinction between coronary occlusion and coronary thrombosis. The former may occur without producing symptoms of heart pain because of the presence of newly developed collateral circulation. Such circulatory change does reduce the blood supply to the heart muscle and angina pectoris may be present if oxygen supply to the muscle is not sufficient to meet the demand. The picture of prolonged heart pain, pallor, lowered blood pressure, leukocytosis and fever should be diagnosed coronary thrombosis and indicates the formation of an infarct of the heart muscle. These patients require at least six weeks of absolute rest.

MEDICAL LITERATURE

IN the Lloyd Roberts lecture with the above title delivered before the Medical Society of London on November 16, 1939 (*The Lancet*, 2: 21, 1939), Sir Robert Hutchison, President of the Royal College of Physicians, discusses in detail the bulk of medical literature in the world, its quality and how to cope with the enormous surfeit of it which he takes pains to show really exists. In his analysis of the periodical situation he quotes freely from the Schorstein Memorial lecture on "Medical Periodical Literature" by Professor William Bulloch, F.R.S. (*British Medical Journal* 2:810, 1935), stressing particularly the latter's estimate that there are over 5,000 medical periodicals of one sort or another in the world, while others, he states, have put the number as high as 7,000. Put in another way, states Professor Bulloch, "there have been, on an average, two articles published on tuberculosis alone every day for the last forty years."

Inferentially the blame for this situation is placed at the door of the United States, for it is stated in the Hutchison lecture that Great Britain produces about 130 medical journals and everyone knows that the output of the other European countries is not large. But an examination of the 1938 A.M.A. Directory shows that in this country, including the Philippine Islands, Puerto Rico and Canada, there are but 224 medical journals altogether. Where, then, are the other thousands? The answer is to be found in the Bul-

loch lecture where, in an attempt at facetiousness, the well known pathologist gave the names of some, such as the "Doctor's Factotum." Evidently every trade organ in this country has been included in the term "medical periodicals of one sort or another" and this, to us, is patently ridiculous. Regrettably it weakens the argument but it does not alter the fact that nevertheless there is plenty of room for improvement in the field of regular medical literature everywhere, both in the periodicals and in the books. The rest of the Hutchison lecture contains some very valuable discussion of the weaknesses which still infest both fields and makes a number of useful suggestions. It is unfortunate that it is marred by the irrelevancies and inaccuracies which have been pointed out.

GILBERT COTTAM.

ECONOMIC QUESTIONS

BEING doctors and not political economists, here are a few questions we should like to have answered.

Why do wealthy citizens establish Foundations, the activities of which are largely devoted to the establishment of socialism in medicine?

Why do certain individuals who have prospered by reason of their own industry and initiative become parlor socialists and even communists, ignoring the fundamental biological necessity so tersely stated in the phrase "Root, hog, or die"?

Can human nature resist the temptation to spend money in riotous living and to ignore the virtue of saving if there is assurance that thrifty neighbors through taxes will furnish support in later years of poverty?

Is there any reason why the medical profession should be socialized and not lawyers and merchants?

Why do certain advocates believe that a governmental bureau with a large personnel and a lot of red tape can supply medical care to our citizens without an enormous increase in total cost?

Why do the same individuals believe that in a panel system patients will receive the same individual medical attention as they now do?

What country with any form of government sickness insurance has better health and a lower death rate than the United States?

What in case of free medical service is to prevent neurotics from making life intolerable for salaried government physicians by reason of needless day and night calls?

What reason is there to believe that there would be a common objective for the worker relating his subjective symptoms for the purpose of obtaining certification for sickness benefit, and for the doctor whose object is to cure the worker?

Why does our government continue to buy gold at a pegged price when gold is no longer a medium of national or international exchange?

Why does our government continue to buy silver at a pegged price when it is considered the height of folly for an individual to pay more for anything than is necessary?

Why does our government deliberately favor higher wages and thus higher cost of production, which everyone knows necessitates a lowering of consumption of goods, a higher tariff and less foreign trade?

Why do some believe that the economic law of supply and demand can be circumvented by legislation?

OF GENERAL INTEREST

Dr. Max Kern of Rogers, Minnesota, son of Dr. M. J. Kern of Saint Paul, has moved to Freeport, Minnesota.

* * *

Dr. William J. Noonan has opened an office at 515 Medical Arts Building, Minneapolis, for the practice of urology.

* * *

Dr. H. T. Sherman, formerly of Mantorville, has moved to Nerstrand, Minnesota, taking over the practice left open last October when Dr. R. Wilkowske moved to Owatonna.

* * *

Dr. Robert Maves, who has been associated with Dr. F. C. Westerman in Montgomery, has purchased a practice in Burien City, Washington, and will follow his profession in that city.

* * *

Dr. Lloyd Gilman, who has been practicing medicine at Osceola, Wisconsin, has moved to Atwater, Minnesota, where he will share offices with his brother, Dr. Donald Gilman, who is a dentist.

Dr. C. L. Farabaugh, who has had his practice in Owatonna since 1931, has announced the opening of offices at 3657 Emerson Avenue North, Minneapolis. He will specialize in treatment of diseases of the eye.

* * *

Dr. C. B. Abbott, Springfield, Minnesota, is in Mexico City, recuperating from a cholecystectomy. He expects to return to his practice in Springfield the latter part of March.

* * *

Dr. David Schuele, who has been associated with the Gamble Clinic of Albert Lea for more than two years, is now located in Chatfield, Minnesota. He will be associated in practice with Dr. Charles Wodruff, who has been practicing in Chatfield for thirty-nine years.

* * *

Dr. A. C. Strachauer has been named chief of staff of Eitel Hospital for 1940, succeeding Dr. J. C. Litzenberg. Dr. Walter Ude succeeds Dr. E. A. Bedford as assistant chief of staff and Dr. Theodore Stebbins succeeds Dr. U. S. Anderson as secretary.

* * *

Dr. Edward D. Churchill, John Homans professor of surgery at Harvard Medical School, will deliver the seventh E. Starr Judd Lecture at the University of Minnesota, March 14, 1940. His subject will be "Surgery of the Lungs."

* * *

The Foundation Prize of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons of \$150 is again open to internes or those practicing this specialty. Manuscripts are due by June 1, 1940. For further information, address Dr. James R. Bloss, Secretary, 418 Eleventh Street, Huntington, West Virginia.

* * *

Dr. Arthur E. Karlstrom has been appointed director of hygiene and health education in the Minneapolis public schools. Dr. Malvin J. Nydahl, whom Dr. Karlstrom succeeds, has accepted appointment as head of the crippled children's bureau of the state social security department. Dr. Karlstrom, a graduate of the University of Minnesota Medical School in 1935, served as director of the public schools' child study department for a year and one-half after internship at the University Hospital and a teaching fellowship at Strong Memorial Hospital in Rochester, N. Y. He also has been clinical instructor of the university pediatrics department and a member of General hospital staff.

The Finnish Relief Fund

Physicians are urged to make any contributions they can to the Finnish Relief Fund sponsored by Mr. Herbert Hoover, and to be devoted to supplying the Finnish civilian population with food and clothing. The need is great. Even small contributions will be gratefully received. All checks should be made payable to the Finnish Relief Fund, Inc., and sent to the Medical Division of the Fund, 420 Lexington Avenue, New York City.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association

W. F. Braasch, M.D., Chairman

REPORT OF THE SURVEY OF MEDICAL CARE

The report of the Survey of Medical Care in the United States which has been compiled by the Bureau of Medical Economics of the American Medical Association has just been published. It includes reports from thirty-eight constituent state medical societies and 623 of the component county medical societies. Replies were received from 22,397 physicians and dentists. Of this number 17,000 were returned by physicians, who constitute 27 per cent of the physicians in active practice in the areas surveyed.

This survey covered a total population of 49,278,083 and is more fully representative of both urban and rural populations than any previous similar investigation. The survey was not devised primarily to produce a statistical report, but rather to obtain a consensus of opinion after a study of the facts by those close to the situation as to the need and supply of medical care.

Value Enhanced

The value of the report is enhanced by the cooperation received from a large number of allied agencies. Other than from physicians and dentists, replies were received from 16,290 sources. These include reports from the following allied organizations:

Hospitals—1,336
Nurses organizations—1,888
Health Departments—839
Welfare and Relief Agencies—1,896
Schools and colleges—3,853
Other organizations—1,963

The combined data turned in by these various agencies should give a fairly accurate idea as to the need and supply of medical care. Not alone is this information made available, but practical suggestions for the improvement of conditions found were made in many instances. Examination of the data reported and of the opinions expressed justifies the conclusion that there is no

important section of the population of the United States that now fails to receive the medical care it *needs* and *desires*.

Care of Indigent Inadequate

It would seem that the greatest inadequacies exist in the indigent groups which are supposed to be looked after by government agencies. This is indeed a sad commentary on a situation which might be taken care of if the agencies involved were properly managed.

The report is quite contrary to the data on which the National Health Program is based. It is high time the public was brought to realize the fallacies and exaggerations embodied in the National Health Report.

Frank criticism of the conditions involving medical care in various localities and detailed suggestions for their improvement are made by many of the county societies. These are specific, constructive criticisms as to defects for which a remedy is available and a program for future improvement is included in many instances. The following statements are quoted from the Report of the Survey:

Program Is Diverse

"The picture that takes shape out of all these details of facts and opinions appears to be one of a fairly well correlated and constantly improving program of medical care. This program has not been planned in detail and then applied by authority, but has grown and developed with infinite diversity to correspond to an infinite variety of local and historical differences. This program has been constantly expanded by the inclusion of new elements and the assumption of new tasks. Its organization is flexible and coöperative rather than fixed and authoritative. It includes a multitude of public and private organizations which, in spite of occasional disagreements and friction, in the majority of localities have agreed upon methods of coöperation and division of labor. It is free to experiment on any one of scores of fronts without involving an entire national movement in local

failures, while successful experiments are quickly and widely adopted.

Meets Pragmatic Test

"This program meets the practical, pragmatic test—it works. Measured by the statistical test that is applicable to any phase of medical care—that of morbidity and mortality—it has proved to be more efficient in attaining its purposes—to reduce illness and to postpone death—than any of the autocratic and official programs existing in other countries and which are urged for adoption here. The development of this program for the future depends upon the continuance of the same methods, constant investigation and study to discover defects, cautious experimentation with methods to correct those defects and development of such of these experiments as prove sound, practical and serviceable.

Foundation Laid

"This survey not only sought to bring out the facts concerning the need and supply of medical care, but to lay the foundation for whatever changes might be helpful in meeting any deficiency in the supply of medical care. County medical societies were asked to assemble the original forms and to analyse the facts which they revealed. It was suggested that medical societies should also assemble any additional information bearing on the subject of the survey and should then prepare a report, copies of which were to be sent to their respective state medical societies and to the American Medical Association. It was suggested that this report might well form the basis of proposed improvements in the local medical and health programs. Not all of the county medical societies carried out all of the details of this suggestion. A considerable number, however, did prepare such reports, some of them constituting fairly large bound volumes of typewritten or mimeographed material which contained suggestions as to the methods of introducing needed improvements.

Open to Examination

"The state medical societies also were asked to assemble the county society reports and to include a number of items of information applying to the state as a whole. Some of the state medical societies also prepared extensive bound volumes of the information assembled in the course of the study and the societies' recommendations as to future action. Many of the state and county medical society reports state that measures have already been taken to supply some of the deficiencies which the survey revealed. It is already evident that one of the results of the survey will be the introduction of appropriate improvements, some of them of a minor character and others of a more extensive nature requiring changes in the general program of medical care. Furthermore, the material assembled in this survey is available for the development of future programs. This material is open for examination by any public or private body or individual interested in improving the conditions of medical care in this country."

Will They Take Heed?

Now that these invaluable data are available for investigation by everyone interested, one wonders whether the federal authorities will take advantage of the opportunity which has been offered to them by the American Medical Association. Federal health authorities are given an opportunity in this Report to determine health conditions as they actually exist in the various localities, the deficiencies are clearly described and suggestions are made as to how to best correct them. One hesitates to make any prediction, but if government officials run true to form, the chances are that they will pay little or no attention to this invaluable survey.

Copies of the survey report are available to anyone applying to the office of our Association Secretary. Anyone who makes a careful study of its contents will be amply repaid. The Bureau of Medical Economics of the American Medical Association, under the able guidance of Dr. R. G. Leland, deserves the greatest praise for bringing its efforts to such a successful conclusion.

If the survey does nothing else, it brings out in bold relief the value of paragraph No. 5 of the platform of the American Medical Association, which calls for "The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration."—W.F.B.

THE NATIONAL PHYSICIANS' COMMITTEE

Organization of the National Physicians' Committee has gone on apace. Through the energetic efforts of the Executive Administrator, Mr. John M. Pratt, a number of pamphlets have been distributed to all of the physicians of the country, informing them as to the objectives of the Committee, with suggestions as to action which might be taken.

There is no question that the best form of propaganda regarding the activities of the medical profession and its influence on the nation's health today is by word of mouth. In other words, if each physician would take upon himself the duty of informing his patients and friends as to the facts involved, we should accomplish a large part of our objective. There is no form of publicity quite like direct personal propaganda.

It would be advisable for members of the National Committee in each locality to get together

and formulate some program so that they can appear on the program of community or other groups and give them the information that we desire to put across.

If there is any lack of ideas on this subject, information can be gained by a careful perusal of the various pamphlets entitled "The Achilles Heel of American Medicine," "Priceless Heritage" and "The Minute-Men of American Medicine," which have been put in the hands of nearly every physician. The success of this movement is up to every individual member.

If additional material is desired, a discussion of the various portions of the platform of the American Medical Association would be most appropriate and would furnish plenty of campaign material.

FROM THE NATIONAL CONFERENCE ON MEDICAL CARE

Minnesota's conference off-spring, the Northwest Regional Conference, became a full-fledged national meeting in Chicago, Sunday, February 11, and some sixteen Minnesota physicians were among the 225 representatives from twenty-four states who attended.

Group medical care, group hospitalization, public welfare programs, the general tax problem and federal aid to the states in the extension of health programs were chiefly discussed on the program because medical leaders everywhere are pre-occupied with these and related problems.

It is to be hoped that proceedings of the conference will be published in full. In the meantime, the following brief résumé may be of more than passing interest as an indication of the extent and liberalism of medical endeavor today.

Hospital Service Extended

In Missouri, for instance, group hospital service, on much the same pattern as our Minnesota Hospital Service association plan, is being extended to rural districts. Dr. Carl F. Vohs, St. Louis, outlined the service, declared that it was operating successfully in Missouri and said that rural contracts are being sold through Missouri Farm Bureaus.

In New York City group hospital service has had difficulties in the last year or two and is now being re-habilitated. The fault, according to Mr. David H. McA. Pyle of New York, was not in

group hospitalization itself, but in the former policy of selling individual contracts. Many individual contracts had to be canceled to set the plan on its feet again. Hospitals are coöperating to tide the plan over the rehabilitation period.

Michigan—Off to a Start

In Michigan, the new Michigan Medical Service is just getting off to a good start, according to Dr. Henry R. Carstens of Detroit. The service went on sale on January 1, 1940, and no figures are available, yet, to indicate how popular the service will be. It is now being tied up with a state plan for group hospitalization and is already taken on, according to Dr. Carstens, by some one of the biggest of Michigan's big industrial plants.

Farm Security Plans

Dr. R. C. Williams of the United States Public Health Service, reported that no less than 420 county medical societies are now coöperating with the Farm Security Administration to provide medical care for Farm Security clients in many parts of the United States. Details of the plans differ in different localities but all operate on the principle that the client will pay his doctor with money loaned to him by the administration and that the doctor will adjust his charges to the ability of the client to pay.

Choice in Chicago

In Chicago the right of relief clients to their choice of physician has been preserved and protected—in contrast to the situation in many other large cities of the United States, according to Dr. C. H. Phifer. Committees which are, in most respects, comparable to our County Contact Committees pass upon fees, settle differences. Of course, Cook county hospital and other public clinics are used.

Pitfalls

Dr. R. G. Leland warned of several pitfalls that may lie in wait for unwary states which accept Federal funds to set up programs otherwise entirely beyond the ability of the states alone to support. One of them lies in the unreliability of Federal funds which depend upon appropriations from Congress. If Federal funds are withdrawn, it will be up to over-burdened state legislatures to supply the funds.

Relief in Minnesota

Minnesota's re-organized relief program was outlined to the conference by Dr. A. W. Adson,

of Rochester, chairman of the Medical Advisory Committee to the Division of Social Welfare. For many years the handling of medical relief has been more satisfactory in Minnesota than in many other states. A ground-work of coöperation between doctors and welfare officials has been laid which will be utilized to the advantage of both in the official new system of county contact and advisory committees. These committees act in advisory capacity to county welfare boards with the state committee acting in a similar capacity to the state division and also as an appeal body from the county organizations.

The President Listened

President Roosevelt listened carefully to what doctors and hospital representatives had to say at the recent conference on the proposed new hospital building program, Dr. E. H. Cary of Dallas, chairman of the American Medical Association's Legislative Committee reported. This time he incorporated some of their suggestions in his message to Congress and, as a result, the bill introduced by Senator Wagner proposes that hospitals be provided on a basis of local need and not on a basis of matching funds, regardless of local needs. The National Health Program as previously drawn up is not dead, however, in the opinion of Dr. Cary. It may be revived at any time.

"If the Battle Is Lost"

Aid and comfort as well as good advice were to be found in a fine address by Mr. Paul G. Hoffman, president of the Studebaker Corporation. Said Mr. Hoffman:

"Industry faces much the same threat of socialization as medicine and industry, like medicine, must solve its own problems to protect itself from government interference. The tax problem underlies some of our difficulties. Taxes are increasing and must be curtailed before business can recover. We have leaders in Congress who are capable of handling the tax problem if left alone; but they must be given a chance.

"I admit to a fundamental recoil against socialized medicine. Bureaucratic control of medicine would, in my opinion, exert the same deadening influence in your profession that it has in the industrial field. But again, judging solely from what I have read, the problem is there and it has not been fully met. . . . With reduced national income and reduced individual income, in order to maintain automobile volume we had to bring down both the original cost and the upkeep of cars. Many millions of dollars were spent in market research on this problem. . . . I raise the question as to whether

the medical profession has made a similar survey to find out what type of service the average person requires and what he can afford to pay for it. . . . I raise the question as to whether you have applied your fine professional brains to a challenge of every item of the cost of medication, including hospitalization, to make certain that you are giving the customer the best break you can for his dollar. These questions come to my mind because of my confidence that better answers can be found for them by private medicine than by socialized medicine. . . . If there is anything at all to the questions, I urge quick action because, if the battle for freedom is lost on the medical front, our fight to preserve free enterprise in business will be made that much tougher."

Complete Picture

The Connecticut Survey of Needs and Supply of Medical Care is being carried on, not by the medical association, but by the state government. Believing that a survey by physicians would be open to the charge of partiality, Connecticut doctors went to the governor, according to Dr. Creighton Barker of New Haven. Funds were appropriated and a study which it is hoped will give a complete picture of medical care in Connecticut was started. The survey is not yet completed.

Best Method

Many methods of reaching and educating the public were discussed by Dr. Edward J. McCormick of Toledo, but, the best method said Dr. Morris Fishbein, editor of the *Journal of the American Medical Association*, by way of comment, is still the direct approach of the physician himself to his patient and friends.

GROUP HOSPITALIZATION IN DULUTH

Seldom has any mutual health scheme taken hold of the Duluth public with such popular approval as has the hospital service plan.

In Canada and the United States four and a half million subscribers, according to figures submitted, are enrolled in non-profit hospital plans. Some groups have had hard sledding. Two states in the union have enrolled over 10 per cent of the population—New York and Minnesota. Forty-two per cent of the population of Duluth is enrolled directly or indirectly and this fact was the principle topic of discussion at the Mid-Winter Conference of Hospital Service Plans held in Pittsburgh in January, 1940.

The Duluth hospitals collected, on account of patients enrolled, \$110,000.00 in 1939. This

amount was spent on about four thousand of the subscribers. The local office contributed its share to the half million reserve carried by the Minnesota Hospital Association. Ninety-eight per cent of these four thousand were in the hospital less than twenty-four days. Women used more of the service than men. The lower income group used the service less than the higher income group; the "whiter the collar" the more it was used.

A rough cross section of opinion among physicians was that their collections were not materially better as a result of the hospital plan. A few found some improvement.

The hospitals on the other hand were filled much of the time in 1939 and patients expressed enthusiasm for the scheme.

The Duluth office expressed its appreciation of the coöperation from local physicians. The average hospital stay in Duluth was less than that in the Twin Cities. To keep the cost to subscribers low means to keep the hospital stay short.—A.N.C.

PLAN TO LOWER COSTS—RAISE STANDARDS

An interesting new development in group health plans is the Group Health Federation of America, Inc., which has just completed its organization, adopted its constitution, by-laws and policies and elected officers.

This federation is composed of "voluntary group health plans in a coast to coast network," to quote a recent bulletin. Among them are the Ross Loos group of Los Angeles, the Group Health Association of Washington, D. C. (storm center of the District of Columbia controversy) and others.

According to its constitution and by-laws the federation aims to promote plans for providing good medical care to people of moderate means at a cost which they can afford and on a basis where they can pay their own way without resort to charity. The organization will "establish and maintain among its members high standards of personal medical care. It will also seek to unify and coördinate the activities of member groups and exchange experiences and information so that each may benefit from the knowledge gained by others.

"—To Complete the Work"

"In essence the Federation hopes, over a period of time, *to complete, in the field of group medicine, the work that has been done by the American Medical Association in raising standards of practice for the individual physician* (italics are ours).

Many names familiar for their association with the earlier promotions of the Foundations or as leaders of individual enterprises which have been much in the news appear among the officers and directors. They include as officers Dr. Mahlon D. Ogden, Trinity Hospital, Little Rock, Arkansas, president; Dr. Michael Shadid, Farmer's Union Coöperative Hospital Association, Elk City, Oklahoma, vice president; Charles A. Marlies, Group Health Association of New York, secretary-treasurer, and Martin W. Brown, assistant secretary. On the Board of Directors are Dr. A. L. Curtin, Milwaukee Medical Center, Milwaukee; Michael M. Davis, Committee on Research in Medical Economics, New York (formerly with the Rosenwald Fund); C. G. Gorman, Group Health Association, Washington, D. C.; Mr. Marlies; Dr. M. D. Ogden, Trinity Hospital, Little Rock, Arkansas; Dr. Elmer Richman, Wage-Earners Health Association, St. Louis, Mo.; Dr. Kingsley Roberts, Bureau of Co-operative Medicine, New York City; Dr. Shadid; Dr. Joseph Still, Greenbelt Health Association, Greenbelt, Maryland; Dr. C. R. Wiley, Civic Medical Center, Chicago.

GROSS MISDEMEANOR

Occasionally, recipients of Old Age Assistance see an opportunity for additional assistance in the allowance made for medical care.

To secure it, all they have to do is to get the doctor to declare they are in regular need of medical service. The doctor is not often a party to such maneuvers but now and again he may yield out of kindness of heart—and ignorance of the fact that he is committing a gross misdemeanor. The law on the matter is explicit. It reads as follows:

Laws of 1937
Section 21

Any person who has obtained or who, by means of a wilfully false statement or representation, or by impersonation, or other fraudulent device, hereafter obtains, or attempts to obtain, or aids or abets any person to obtain:

(a) An old age assistance certificate to which he is not entitled;

(b) More old age assistance than that to which he is justly entitled;

(c) Payment of any forfeited installment grant;

(d) Or who knowingly aids or abets any person buying or disposing of the property of the recipient with the intention to assist in receiving or qualifying any person for old age assistance;

(e) Or any recipient who transfers any personal property exceeding \$300.00 in value without first giving notice to the County Agency of his intention to do so; shall be guilty of a gross misdemeanor.

HOSPITAL REPORT

In view of Senator Wagner's new bill for an emergency appropriation for hospital building, a brief review of the record of hospitals already built with Federal aid in the last six and one-half years should be of interest. These hospitals, it should be noted, do not include any veterans' hospital construction, Federal sanitariums, Indian or military projects or Federal prison infirmaries.

107,849 New Hospital Beds

A recent PWA report on this construction appears in the *Congressional Record* of January 30, 1940:

"During the past six and one-half years the Public Works Administration has made \$176,928,556 in allotments for 743 hospital projects involving the construction of 2,056 buildings providing 107,849 beds. The total construction cost of this portion of the PWA program has been estimated at \$297,253,706. They are located in all the states, the District of Columbia, Alaska, Hawaii and Puerto Rico and approximately 45 per cent of them are located in states that do not contain large metropolitan areas. Many of the hospitals were constructed in communities which heretofore had been without hospital facilities.

Five Years' Growth

"The technical committee appointed at the President's National Health Conference in 1938 determined that the normal increase in hospitals beds has been 25,000 a year. As a result of PWA construction there has been the equivalent of five years' normal growth during the six and one-half years covered.

"PWA-financed non-Federal hospitals are classified into general hospitals, those special hospitals needed in many sections of the country to bring the Nation's hospitals facilities to an adequate standard. The President's technical committee advised that 36,000 beds a year for ten years should be added to the existing supply to adequately meet the demand and in addition the setting up of some 500 health and diagnostic centers in areas now inaccessible to hospitals.

Applications Returned

"This nation-wide need for additional hospital facilities was indicated in the fact that when PWA returned 5,043 applications to public bodies on September 6 because of lack of additional funds there were among them 203 applications for hospitals and institutions with an estimated construction cost of \$105,-486,892."

New Beds in Minnesota

In Minnesota there were 21 hospital projects built providing 42 new buildings and 1,926 additional beds at a cost of \$4,745,377. In Wisconsin there were 18 new hospital projects, providing 40 additional buildings and 1,074 beds at a cost of \$3,925,980. In Iowa, there were 19 projects providing 18 new buildings and 855 beds at a cost of \$1,900,834. The largest number of new hospital beds were provided with PWA aid in Illinois (10,582), in New York (9,721) and in Pennsylvania (8,516).

In addition to this vast amount of civilian hospital construction there have been 152 Federal hospital and sanitarium projects costing \$37,002,863. These projects, including veterans' hospitals and sanitariums, Indian and military hospitals and Federal prison infirmaries, have added an additional 13,911 beds to the nation's hospital capacity, making a total with the non-Federal figure of 121,760 beds.

"WE CAUTION OUR READERS"

For those who were lulled into a false sense of security by the President's birthday message, an editorial which appeared in the last issue of the *Pittsburgh Medical Bulletin* is printed below in full. It is evident that the Wagner bill of 1940 is far from innocuous and the best thought and advice from medical and hospital authorities should be sought before an "experiment" of far reaching consequence is inadvertently fixed upon the statute books.

THE LONG TENTACLES OF BUREAUCRACY

In last week's Bulletin we promised to print in this issue the text of S. 3230, another bill introduced by the Prussian-born Senator Robert F. Wagner of New York. We cautioned our readers at the same time when reading the bill to measure its assertive provisions with their possible distortion through amendment or in subsequent actual administration with the seven guiding points previously proffered President Roosevelt by committees from the American Medical Association and the various national hospital associations.

It will be noted that the bill differs from President Roosevelt's recent message to Congress on the subject of his pet medical service project—the erection by the Federal government of approximately 50 small general hospitals in localities where the need for same has been established and evidence of ability to maintain

them by local funds has been demonstrated. For instance, the bill does not stop with the provision by the current session of Congress for $7\frac{1}{2}$ to 10 million dollars for the construction of such hospitals, but in Section 2 opens wide the "pork barrel" through \$10,000,000 for the year ending June 30, 1941, and for each fiscal year thereafter such sums as the Congress may deem necessary for carrying out the purposes of this act. Also, amounts appropriated under this bill shall be available until expended.

Section 9 opens up an unexpected avenue for the allocation of funds by the President through authorization for the appropriation in each succeeding fiscal year of such amounts as the Congress may deem essential for "the training of personnel deemed necessary" by the Public Health Service for administering the provisions of S. 3230. This at once suggests medical schools definitely under Federal control. In the face of recent commitments by the President of the American Public Health Association and by representatives of the U. S. Public Health Service at the former organization's 1939 meeting in Pittsburgh to the effect that public health activities should now be rapidly broadened with Federal funds in all the states to include more and more of the "curative" phases of medical practice, such angles to any proposed health legislation definitely lengthen the tentacles of bureaucracy.

That our readers may have authoritative bases from which to judge all proposed health legislation in discharging their public duty to discuss such proposals with other intelligent members of the community, i.e., with taxpayers, voters and legislators, we publish again in this issue the recent health legislative platform of the American Medical Association and the seven points governing specifically all proposed new governmental general hospital construction.

Individuals or organizations that see fit to ignore the dangers of advancing the current political philosophy new to the United States "national socialism," should still be cautioned when they engage in discussion of the advisability of seeking new or additional general hospital facilities for a community, a county, or a district, to become acquainted with certain local and fundamental facts: What is the population per square mile in the district? What is the existing general hospital bed capacity, as well as bed occupancy?

Finally, we repeat to our medical readers the caution expressed on page 94 of the Bulletin for February 3, 1940; namely, when new general hospital construction is under consideration, strive consistently, wherever and whenever they are to be located, for competency, free from political domination in expenditures and the professional "staffing" of government-built, locally supported general hospital projects; also, renew your vigilance regarding the future of any medical or social legislation to which the name of Senator Robert F. Wagner is attached, more especially in the face of the recently announced fact that President Roosevelt's Interdepartmental National Health Program Committee, under the chairmanship of Miss Josephine Roche, is "on the loose" again.

"YOUR INSURANCE POLICY"

(Monthly Editorial Prepared by the Medical Advisory Committee)

In a recent communication directed to the chairman of the Medical Advisory Committee was the following paragraph:

My contacts with the doctors the last few years have convinced me that the doctors themselves are their worst enemies and most of them are more or less indifferent to things of their own interest until something happens to affect their pocket book."

How often have you inspected or read your policy of malpractice coverage? Do you know the various provisions in the policies as to the amount involved should you be sued? Is your associate, your assistant or your partner covered by your protection?

These and many other questions could be asked of you, and the likelihood is that the reader would be astounded at his lack of knowledge of the fundamental facts in his policy:

Why not take your policy to the solicitor who wrote it and accepted your premium, or to your lawyer who can explain its provisions to you today, before you are involved in trouble.

In the worry and hustle of medical practice, we are inclined to minimize the possibility of need for adequate protection, but business is business, as many find to their sorrow. Surely, foresight is better than hindsight.—B.J.B.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

License of Minneapolis Physician Revoked Following Conviction for Manslaughter

In the Matter of the Revocation of the License of Richard J. C. Brown, M.B.

At the regular meeting of the Minnesota State Board of Medical Examiners held at Saint Paul, on February 9, 1940, the license to practice medicine held by Richard J. C. Brown, Negro physician of Minneapolis, was revoked. Brown was convicted by a jury of the crime of manslaughter in the first degree, in the Court of the Honorable Arthur W. Selover, Judge of the District Court of Hennepin County, on November 22, 1939. Brown was sentenced on November 25, 1939, by Judge Selover to a term of not less than five and not more than twenty years at hard labor in the State Prison at Stillwater. Brown had been indicted by the grand jury of Hennepin County on August 29, 1939, following the death of a 22-year-old Minneapolis girl upon whom it was alleged that a criminal abortion had been performed on July 31, 1939, by Brown.

According to the records of the Minnesota State Board of Medical Examiners, Brown was born at Lincoln, Nebraska, January 17, 1893, and graduated from the University of Minnesota, in 1920, with the degree of Bachelor of Medicine. He was licensed that year by examination.

Minneapolis Physician's License Suspended for Three Years

In the Matter of the Revocation of the License of Donald V. Jordan, M.D.

Donald V. Jordan, M.D., 39 years of age, with an office at 126 Oak Grove, Minneapolis, had his license to practice medicine suspended by the Minnesota State Board of Medical Examiners at its last regular meeting on February 9, 1940. The Medical Board had previously issued a citation requiring Dr. Jordan to show cause on that date, why his license as a physician should not be revoked for aiding and abetting a criminal abortion upon a 19-year-old unmarried Minneapolis girl. The girl was taken ill following the alleged abortion and was hospitalized. However, she recovered her health and subsequently made a statement concerning the case. The hearing before the Minnesota State Board of Medical Examiners disclosed that Dr. Jordan was an excessive user of alcoholic liquors and he was notified by the Medical Board to place himself under treatment for that condition.

According to the records of the Minnesota State Board of Medical Examiners, Dr. Jordan was born in Minneapolis on November 17, 1900, and graduated with the degree of Doctor of Medicine from the University of Illinois, in 1928. He was licensed in Minnesota in 1932, by reciprocity with the State of New York.

MEDICAL AND PUBLIC HEALTH EXHIBITS

The Medical and Public Health exhibits at the New York World's Fair, which were attended by 7,500,000 visitors in 1939, will be reopened for the 1940 season beginning May 11, as announced by Dr. Louis I. Dublin, Acting Chairman of the American Museum of Health.

New exhibits, the nature of which will be made public before the opening date, will be added to the Carrel-Lindbergh "heart," the Transparent Man and other dramatizations of medical science which vied last year with such industrial features as the General Motors Futurama and the American Telephone and Telegraph Company's "Voder" as drawing cards for Fair visitors.

The outstanding value of the Medical and Health exhibits in spreading a knowledge of hygiene among millions of persons is emphasized by Dr. Thomas Parran, Surgeon-General of the United States Public Health Service, in the following letter to Dr. Dublin:

"It is gratifying to learn that the continuation of the Medicine and Public Health Building at the New York World's Fair is assured for 1940 under the direction of the American Museum of Health.

"The unprecedented success of this undertaking last year should give you every confidence that the Museum will continue its high service to mankind.

"The studies of Visitor Reaction in which the Public Health Service cooperated with you clearly show that the exhibit gave to several million people from the United States, Canada and elsewhere, valuable, life-saving knowledge. The unquestioned scientific accuracy of the exhibits and the high grade showmanship under which they were presented were no doubt responsible for the large and enthusiastic audience. I am sure you will have no difficulty in repeating and increasing your marked success of last year.

"With warmest congratulations and best wishes,"

When the 1939 Fair opened, said Dr. Dublin, it was estimated that 3,000,000 persons would view the health exhibits if the Fair's attendance totalled 40,000,000. The number of visitors to these exhibits, however, reached the unprecedented figure of 7,500,000 out of a total Fair attendance of 26,000,000, or approximately one person out of every third visitor attended the Medicine and Public Health Building exhibits.

MISCELLANEOUS

RELIEF FROM STEAMED EYE-GLASSES*

DONALD W. JOHNSON, S.B., M.D.

Fairmont, Minnesota

MOST surgeons who wear glasses are subject to the annoyance of having them clouded by water vapor as the face mask diverts the warm moist breath upward along each side of the nose to condense on the cool surface of the glass, obscuring vision more or less. Various devices have been offered to prevent this very real difficulty, among them impervious masks; metallic inserts; loosely fitting sacs inclosing the whole head. Only more or less successful, these trappings are an added item of expense. They are not always comfortable.

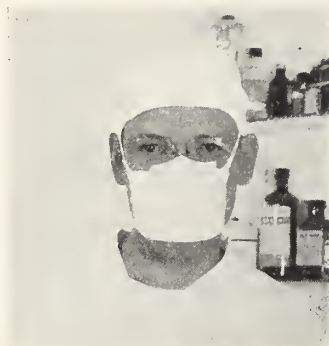

Fig. 1.

Our nurses construct masks from ten thicknesses of 20x12 gauze taped about the perimeter, with the usual four-corner ties of tape. During eighteen years of surgery we have tried all the devices offered to prevent condensation on the glasses, with indifferent satisfaction. The simple expedient of applying a strip of adhesive $\frac{1}{4}$ -inch wide for 3 or 4 inches along the upper edge of the mask and the skin of the nose and face (Fig. 1) has resulted in perfect satisfaction and efficiency. In addition to protecting the glasses from condensation, this arrangement forces exhaled air to filter through the gauze instead of spouting up along the nose, thus increasing protection to the surgical field from air-borne infection. It is also adaptable to every anatomy.

*From the Johnson Hospital.

All behavior is related and it is difficult to distinguish between the behavior which concerns the individual alone and that which concerns others. What a man does about his health, for instance, may concern his family, his business associates, the community and even the entire world.—The Purposes of Education in American Democracy, National Education Policies. Comm., 1938.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR MARCH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis (810 kilocycles or 370.2 meters) and Station WLB, University of Minnesota (760 kilocycles or 395 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

March 2—Rheumatic Fever

March 9—Arthritis

March 16—Gout

March 23—Injuries of Joints

March 30—Exodontia

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The annual meeting of the association will be held at Rochester, Minnesota, April 15, 16 and 17, 1940. Papers on various diseases of the thyroid; dry clinics by visiting guests; and operative clinics by members of the Mayo Clinic staff will occupy the three days of the meeting.

The association is again offering the Van Meter Prize Award for the best essay presented in competition prior to the meeting. The award consists of \$300 and two honorable mentions. Those interested should communicate with Dr. W. Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than March 15, 1940.

THE UNITED STATES PHARMACOPEIAL CONVENTION

In compliance with the provisions of the Constitution and By-Laws of the United States Pharmacopœial Convention, I hereby issue this second call to the several bodies entitled under the Constitution to representation therein to appoint three delegates and three alternates to the Decennial Meeting of the Convention for the Revision of the Pharmacopœia of the United States of America, which is to meet in Washington, D. C., on May 14, 1940.

WALTER A. BASTEDO, M.D.,
*President of the United States
Pharmacopœial Convention.*

February 14, 1940.

NOTICE—In order that the records may be brought up-to-date and checked, that card files may be prepared, and that the other functions of the Committee on Credentials may be performed, it is desirable that the Credentials of all Delegates appointed to attend this Decennial Meeting shall be in the hands of the Secretary, Mr. L. E. Warren, 2 Raymond St., Chevy Chase, Maryland, not later than *March 15, 1940.*

STATE MEETING

Reservations for the Minnesota State Medical Association's 87th Annual Meeting to be held in Rochester April 22, 23, and 24 should be made at once.

Attention of all members has been called to the advisability of making immediate arrangements because the 1940 meeting is more than a month earlier than the customary dates, and now only a little more than a month away.

The meeting is to be held in the fine new Mayo Civic Auditorium and a program of great distinction and interest has been arranged for the three-day session. In addition to the Auditorium meetings, there will be conducted tours to the Mayo Foundation Institute and special physio-therapy demonstrations under the direction of Dr. F. H. Krusen in the Museum building.

Governor Harold E. Stassen will address the annual banquet on Tuesday night, April 23, at the Rochester State Hospital, and the other guest speaker for the occasion will be Mr. Bernard H. Ridder, publisher of the *St. Paul Pioneer Press and Dispatch* who spoke at a recent University of Minnesota convocation on the subject "How the Peace of the World Was Lost."

Another unique feature of the meeting entertainment will be an Open House to be given Monday night, April 22, in the Arena of the Auditorium. The Mayo Clinic and the Olmsted-Houston-Fillmore-Dodge County Medical Society will be hosts for this occasion. There will be a floor show and buffet supper. All visiting physicians and their wives are invited to attend.

Monday's scientific sessions, scientific cinema, and round table luncheons will be conducted exclusively by members of the Mayo Clinic staff. Tuesday and Wednesday sessions will be conducted by other Minnesota physicians and a half dozen famous guest physicians among whom are Dr. Norman Jolliffe of New York City; Dr. Harry E. Mock and Dr. Paul B. Magnuson of Chicago; Dr. John O. Bower of Philadelphia, and Dr. Bernard H. Nichols of Cleveland. The latter will deliver the Russell D. Carman Lectureship annually provided by the Minnesota Radiological Society.

Round-table discussion luncheons on Tuesday and Wednesday will be conducted by Minnesota medical leaders and the guest speakers.

Three-quarters of an hour will be devoted during each morning and afternoon program session to scientific and technical exhibits and the scientific cinema. The Southern Minnesota Medical Society will present its annual medal for the best scientific exhibit submitted by an individual physician at this meeting.

WASHINGTON COUNTY

The regular monthly meeting of the Washington County Medical Society was held on the evening of February 13 at the Stillwater Club rooms.

Royal C. Gray, M.D., psychiatrist to the state institutions, gave a well prepared paper on "The incidents in childhood of psychosis and schizophrenia." The doc-

tor answered numerous questions afterward. E. M. Jones, M.D., Counselor for the Fifth (our) District of the Minnesota Medical Association, was present by request to advise us on some peculiar membership matters that have developed during the last year. The doctor also spoke of the importance of the Officers' Meeting at the St. Paul Hotel on Feb. 24. This meeting will be very important as new ideas and methods in the conducting of county welfare matters, as affected by new rulings, will be discussed by well-posted men from Minnesota and from other states, especially by Dr. Leland of Chicago. Several announcements were made. A letter from Stillwater Post No. 48, American Legion, was read. It requested, in behalf of the Legion, information in regard to blood donors and conveyed an invitation to members of the Society to their March 5 meeting at the Stillwater Armory. The object is to form a blood donor group at the Post here, certainly a very thoughtful and laudable act, which is heartily recommended by this Society. A committee was appointed to meet with them.

E. SYDNEY BOLEYN, M.D., *Secretary*

Dilantin Sodium

The Council on Pharmacy and Chemistry reports that sodium 5,5-diphenyl hydantoinate, originally presented under the name Dilantin, had been redesignated "Dilantin Sodium" and is now marketed by Parke, Davis & Co. as "Kapseals Dilantin Sodium." Dilantin Sodium is an active anticonvulsant and relatively feeble hypnotic, used in the treatment of epilepsy. While the clinical studies of H. H. Merritt and Trace J. Putnam, and of O. P. Kimball, pointed to the therapeutic value of the drug the Council requested additional information. Pharmacologic studies were conducted in the laboratories of Parke, Davis and Company, and clinical investigations were made in a number of institutions, five of them in institutions for the treatment of epilepsy and kindred conditions. The pharmacologic studies show that Dilantin Sodium is of relatively low toxicity when administered orally to rats, rabbits and dogs, and much more toxic when injected intravenously. The side actions reported by one or more of the investigators include dizziness, dry skin, dermatitis, rash, itching, tremors, fever, nausea, vomiting, blurred vision, fatigue, apathy, difficult breathing and swallowing, nervousness, mental confusion and active hallucinations. The Council voted to accept Dilantin Sodium for inclusion in New and Non-official Remedies following receipt of an agreement from Parke, Davis & Co. that it would market the product under rigid restrictions, including those which further experience shall indicate, as well as the following: (a) It shall not be recommended for use by the general practitioner unless he is able to maintain a close (daily) supervision of the patient, until the scope of its usefulness as well as its side actions have been determined more accurately; (b) it is not to be recommended for the treatment of those patients whose seizures occur only at long intervals unless moderate doses of phenobarbital are ineffective or induce disagreeable side actions. The A.M.A. Chemical Laboratory has found the composition of Dilantin Sodium satisfactory. (J.A.M.A., Nov. 4, 1939, p. 1734.)

WOMEN'S AUXILIARY

MRS. A. C. BAKER, Fergus Falls, *President*
MRS. E. V. GOLTZ, 2259 Summit Avenue,
Saint Paul, *Publicity Chairman*

The mid-winter meeting of the State board of the Women's Auxiliary of the Minnesota State Medical Association was held in the Radisson Hotel, Minneapolis, January 23. The president, Mrs. A. C. Baker of Fergus Falls, presided at the business meeting at 10 a. m. Reports from the officers, county presidents and chairmen of various committees were heard and much time was devoted to discussions pertaining to *Hygeia* and Public Health activities throughout the state. A very interesting report was given by Mrs. Baker on the recent meeting of the national board held in Chicago. The following women were elected to positions on the nominating committee: Mrs. Thomas O. Young of Duluth, Mrs. Harry Ghent of Saint Paul, Mrs. George B. Eusterman of Rochester, Mrs. E. S. Mariette of Minneapolis, and Mrs. T. N. Fleming of St. Cloud. Luncheon followed the meeting and Dr. E. L. Meyer of Minneapolis entertained the group with motion pictures which he took on a recent trip to South America. Dr. B. S. Adams of Hibbing was the guest speaker. The meeting was very well attended and the following women attended: Mrs. A. C. Baker, Fergus Falls; Mrs. James Blake, Hopkins; Mrs. Sydney Boleyn, Stillwater; Mrs. T. J. Catlin, Buffalo; Mrs. J. A. Cosgriff, Olivia; Mrs. R. R. Cranmer, Minneapolis; Mrs. L. J. Dack, St. Paul; Mrs. N. S. Dungay, Northfield; Mrs. F. Elias, Duluth; Mrs. E. C. Eshelby, Saint Paul; Mrs. George Eusterman, Rochester; Mrs. T. N. Fleming, St. Cloud; Mrs. Harry Ghent, Saint Paul; Mrs. J. B. Gaida, St. Cloud; Mrs. E. V. Goltz, Saint Paul; Mrs. G. Haight, Detroit Lakes; Mrs. E. M. Hammes, Saint Paul; Mrs. L. P. Howell, Rochester; Mrs. R. J. Josewski, Stillwater; Mrs. O. O. Larson, Detroit Lakes; Mrs. Ernest Mariette, Minneapolis; Mrs. McGath, Rochester; Mrs. Martin Nordland, Minneapolis; Mrs. J. F. Norman, Crookston; Mrs. W. B. Roberts, Minneapolis; Mrs. J. J. Ryan, Saint Paul; Mrs. Theo. Sattermann, Pelican Rapids; Mrs. J. A. Thabes, Sr., Brainerd; Mrs. W. W. Will, Bertha; Mrs. T. O. Young, Duluth; Mrs. H. F. Wahlquist, Minneapolis.

The eighteenth annual convention of the Women's Auxiliary of the American Medical Association will be held in New York City, June 10-14, 1940, with headquarters in the Hotel Pennsylvania. In view of the fact that the second edition of the World's Fair will accelerate advance hotel reservations, it is urged that reservations be made immediately through the Housing Bureau which has been set up by the American Medical Association, namely Dr. Peter Irving, Room 1036, 233 Broadway, New York City, N. Y.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of January 10, 1940

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, January 10, 1940. Dinner was served at 7 o'clock and the meeting was called to order by the President, Dr. James A. Johnson, at 8:15 p. m.

There were fifty-three members and one guest present.

Minutes of the December meeting were read and approved.

The secretary read a letter from Dr. Herbert Davis, of Saint Paul, asking that his name be transferred from the Active to the Senior membership list. This had been approved by the Executive Committee. Upon vote, this transfer was accepted.

The following Memorial to Drs. William J. and Charles H. Mayo was read by Dr. S. Marx White. A motion was carried that this be accepted, spread on the minutes and a copy sent to each family.

THE MAYO BROTHERS

Dr. William James Mayo, born at Le Sueur, Minnesota, June 29, 1861. Died July 28, 1939.
Dr. Charles Horace Mayo, born at Rochester, Minnesota, July 12, 1865. Died May 26, 1939.

To those who knew them best, as did their medical and surgical friends and neighbors in Minnesota, the fact that the elder brother, Doctor Will, was called by death just nine weeks after the loss of his brother, Doctor Charlie, seems almost a corollary of their useful and devoted lives together. During the later years of their father, Dr. William W. Mayo, they delighted to honor him, and with his death that generous spirit continued between them. When opportunity or honor came to one, he saw to it that it was shared by the other.

It is not the intention in this brief memoir to list the honors or recite the achievements of these two outstanding leaders in medicine and surgery. Their fame was national and soon became world-wide. Details concerning the life of each may be found in the July and August, 1939, issues of MINNESOTA MEDICINE, as well as in many other professional and lay publications immediately following the death of each.

To the members of the Minnesota Academy of Medicine the dates of their inaugural theses read before this body and the titles of subsequent contributions to our programs may be of interest.

Doctor Will's thesis entitled "A Discussion of Some Features of Peri-uterine and Peri-typhlitic Abscesses" was read at the meeting of May 3, 1890, and published in *Northwestern Lancet*, Volume X, page 166. From then on he presented papers on various subjects—Cancer and Its Surgical Treatment, Extra-uterine Pregnancy, Cicatricial Stenosis of the Esophagus and Its Surgical Treatment, Diagnosis of Surgical Diseases of

the Kidney, Surgical Treatment of Suppuration, Preliminary Examination of the Surgical Patient, Diagnosis and Surgical Treatment of Certain Diseases of the Stomach, Primary Tuberculosis of the Intestine, Surgical Treatment of Some Benign Affections of the Stomach, Malignant Disease of the Gallbladder and Bile Ducts, Cancer of the Rectum. His last paper presented at an Academy meeting was on Splenic Anemia, read at the meeting of May 21, 1919.

Doctor Charlie's inaugural thesis on "Skin Grafting" was presented at the meeting of March 1, 1893, and published in *Northwestern Lancet*, Volume XIII, page 148. Subsequently papers were read on Brain Lesions the Result of Injury without Apparent Fracture, The Use of Heat in Surgery, and on Prostatectomy. The last paper of record was read on Uterine Prolapse at the meeting of April 1, 1914.

The names of both brothers have been on the list of honorary members of the Academy for many years.

Striking evidence of their organizing and professional genius may be found in the fact that they converted what would have been to most men a handicap, into an advantage unprecedented in the history of medicine. If they had done their work in a great medical center, their abilities would no doubt have been the same, but the performance could not have been so unique. Working in a rural community, these two men wrote their names as masters in their field on the roll which contained such names as Keen, Halstead, Fenger, Murphy and a long list of others of like quality, teachers and leaders in American surgery.

The late Dr. A. J. Ochsner of Chicago has told how in the earlier days he with Will or Charlie, one of the brothers at a time, went to see the work of this or that surgeon who had published some new method or tried some new type of operation, first in this country and later abroad. Learning with avidity it was not long before they themselves were in position to teach. Their lives exemplified one of the glories of medicine handed down from the days of Hippocrates in that he who learns shall pass on freely all he knows to all who seek to know. Learning from anywhere in the world where knowledge was to be found, they passed it freely on. Their teaching was personal, direct and practical. Not only did they give freely to all who visited them in Rochester, but the organizing genius built around their clinic a great center for postgraduate instruction. Untrammelled by tradition and free from control of any kind—governmental or educational—their quasi-isolation and freedom from restraint fostered a following and an audience limited only by the capacity of the physical plant and their personal endurance. With great foresight they sought to perpetuate the values of their situation. The history of medicine in the future must recognize their place in the establishment of coördinated, group effort and in furthering graduate teaching and research in medicine. Dr. William Mayo's long service as Regent of our University gave him an insight into

the needs and the technic of education. The Mayo Foundation coördinated with graduate teaching and research in the Medical School of the University of Minnesota has, as its objective, increase in and dissemination of knowledge in medicine and surgery. The desire of the founders is to return to the people by means of improvement in medicine and surgery that which the people have given the founders.

Many stories and incidents have been current illustrating the differing characteristics of their personalities. They were strong, striking and vigorous, and together they made a real contribution to their times. History has a place for them.

Certain incidents seemed at the time to be of little significance. The importance of these grows in retrospect. Their two operating rooms were side by side before other surgeons came into the group. Visitors then will recall incidents such as follow. Will, in his room, operating let us say on the thyroid or the prostate of a patient, would comment on the superior skill of Charlie in operations in the region, and invite the guests to take the first opportunity to observe his brother at this work. Or Charlie, in his room, operating in the abdomen, would deprecate his own skill, and invite his listeners to study what he truly believed to be the most skillful surgeon in this field, brother Will. The effect was electric. Their belief was genuine, and because they possessed it, it came alive and to be accepted.

These two men with brotherly devotion have lived and taught a lesson which all of us in medicine may learn. Working together with high purpose and for each other and for their common good, their efficiency and performance increased not in arithmetical but in geometrical progression. It was as if together they made not two but four. We may learn that working together and not for ourselves alone, the good and the reputation of each will be enhanced.

Dr. Carl B. Drake, Saint Paul, retiring president, read the following Presidential Address. Lantern slides were shown.

SOME APPLICATIONS OF HYDRODYNAMICS TO THE CIRCULATION*

CARL B. DRAKE, M.D.
Saint Paul, Minnesota

Hydrodynamics is that branch of hydraulics which deals with liquids in motion. As applied to the circulation it is termed hemodynamics and involves a consideration of both physics and physiology. A clinician cannot be expected to delve very deeply into either of these allied sciences but may be pardoned for attempting to present some of the simpler laws of hydrodynamics and their application to clinical problems.

It should be understood that the conditions met in the circulation of the blood are comparable but by no

means identical to the flow of water in pipes. In the circulation we have a pump acting at a variable rate and ejecting fluid into a closed system of elastic pipes of various and varying caliber. The circulatory system is supplied by a complicated nervous mechanism which regulates the heart rate and the caliber of the vessels according to the needs of the organism. The heart too has a marvelous ability to dilate and hypertrophy when there is need for greater output or force.

To consider a few facts concerning the behavior of liquids at rest and in motion:

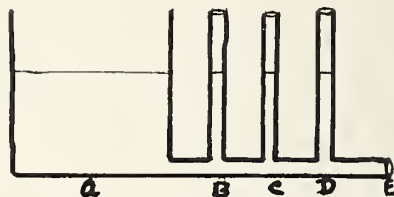

Fig. 1.

Figure 1 represents a tank, *A*, with a horizontal outlet pipe which is closed at *E*. Inserted vertically to the horizontal pipe are a series of tubes *B*, *C* and *D* known as piezometer tubes. Fluid levels in tank and tubes are the same and the side or lateral pressures over equal areas of surface at *A*, *B*, *C* and *D* are equal and are measured by the height of the columns of fluid in the tank and piezometer tubes. Thus fluid possesses potential energy due to its elevation and at areas *A*, *B*, *C* and *D* is measured by the height of the fluid irrespective of the quantity of fluid in the tubes or tank.

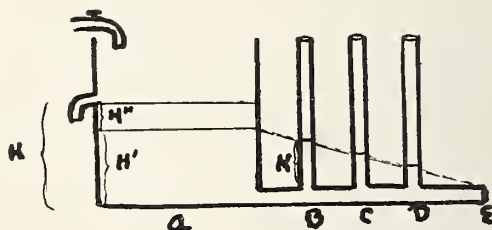

Fig. 2. From Gladstone.

In Figure 2, the outlet at *E* is open and the fluid level in the tank is maintained at a constant height *H*, by water from a faucet and an overflow. Water will flow from the outlet *E* at a certain rate and will possess a certain kinetic energy due to its velocity. The potential energy possessed by the fluid in tank *A* has therefore been converted into kinetic energy. Not all, however. A certain amount has been used to overcome resistance due to friction in the flow of the water in the horizontal tube. The amount of potential energy used to overcome friction is represented by the height *H'* and the remaining height *H''* represents the potential energy converted into kinetic energy at *E*.

The fluid levels in tubes *B*, *C* and *D* are successively lower than the level in *A* and represent the side pressures at *B*, *C* and *D*. Since the velocity in the hori-

*Presidential address before the Minnesota Academy of Medicine, January 10, 1940.

zontal tube is the same at *B*, *C* and *D* the loss of pressure in tube *B*, for instance, is due to the pressure required in overcoming friction from *A* to *B*, and the height in tube *B* represents the pressure necessary to overcome the frictional resistance from *B* to *E*. The blood vessels which leave the aorta do so at right angles and thus serve as piezometer tubes. Thus the pressure in the brachial arteries represents approximately the pressure in the aorta and is not directly affected by changes in velocity head in the aorta.

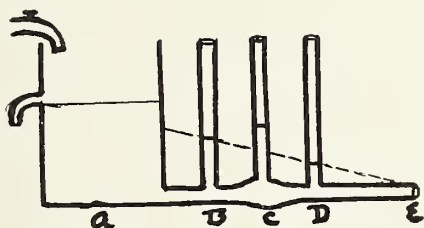

Fig. 3. From Best and Taylor.

The pressure head remaining constant, the velocity of fluid passing through a tube is inversely proportional to the cross section (sectional area) of the tube.² Thus in Figure 3 the velocity of the liquid at *C* is less than at *B* or *D*. Lateral pressure is inversely proportional to the velocity. Thus the fluid level in tube *C* is higher than in tube *B*, indicating a higher lateral pressure at *C*. The velocity however at *D* is the same as at *A*. Thus in an aneurysm of the aorta the velocity in the dilated portion is less and the lateral pressure greater. The greater pressure tends to further dilate the weakened wall of the aneurysm with further slowing of velocity and increase of pressure, a vicious circle.

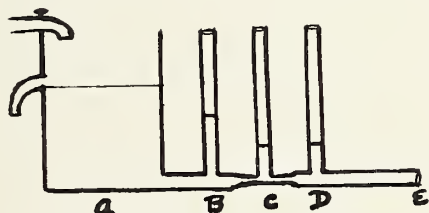

Fig. 4. From Best and Taylor.

Fig. 5. From Howell.

According to the same laws the velocity in the narrowed tube at *C*, Figure 4, is increased and the lateral pressure is less as shown by the lower fluid level in tube *C*.

In Figure 5 a tap partially narrows the lumen of the tube at *X*. This results in a sharp lowering of the lateral pressure in tubes *F* and *G* beyond the narrowing.² This is the situation in coarctation of the aorta, in which condition the pressure beyond the narrowing, including that in the legs, is markedly diminished. The heart compensates by increasing the pressure above normal, proximal to the coarctation, and hypertension is found in the brachials.

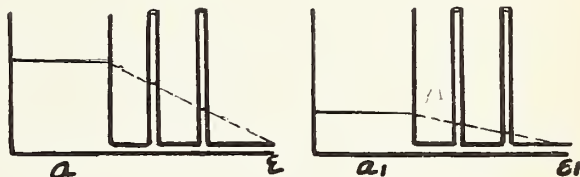

Fig. 6.

The cross section of a tube remaining constant, the velocity of the fluid in the tube is proportional to the pressure gradient. Thus in Figure 6 the higher pressure in *A*, than in *A1*, results in a greater velocity at *E*, than in *E1*. In hypertension the pressure is increased because the arterioles are narrowed. The velocity in the arterioles must be increased if the heart output is unaltered. Weiss found the average cardiac output in hypertension within normal limits.

Friction offers resistance to the flow of liquid through a tube and this friction varies with the surface area encountered by the liquid. At low velocities this frictional resistance is very little. At moderate velocities the frictional resistance varies as the velocity of the fluid while at high velocities it varies as some power of the velocity. This friction occurs not solely at the contact of the fluid with the sides of the tube² for it has been found that fluid does not flow through a tube as a column, and every portion of the fluid does not flow at the same velocity. Instead there is a layer of fluid next to the tube which moves slowly, while successive layers of fluid towards the center move more and more and the greatest velocity occurs in the center of the tube. Friction occurs for the most part between these peripheral layers of fluid. For this reason the frictional resistance is probably not greatly increased in atheromatous vessels.

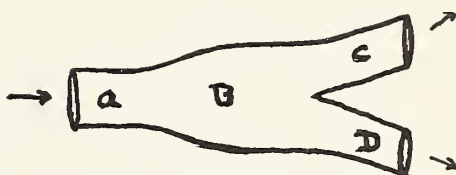

Fig. 7. From Gladstone.

Figure 7 shows fluid passing from *A* to *B* and to *C* and *D*, all of which areas are assumed to lie in the same horizontal plane to eliminate the effect of hydrostatic pressure. The cross section at *B* being greater than at *A* the velocity of the stream at *B* is less and the lateral pressure greater than at *A*. The sum of the

cross section at *C* and *D* being greater than at *B*, likewise the velocity at *C* and *D* is decreased from that at *B* and the lateral pressure tends to be increased. However, as fluid flows through tubes its lateral pressure head tends to decrease because of frictional resistance, and this resistance varies with the length of the tube, i.e., is proportional to the frictional surface encountered. The frictional surface per unit of length in tubes *C* and *D* is much greater than the frictional surface at *B* so that the friction effect of the greater surface on the pressure more than counterbalances the increase in pressure in *C* and *D* due to diminished velocity and results in an actual decrease in pressure at *C* and *D*.

Thus in circulation of the blood as arteries leave the aorta the cross section of the arterial field is increased, which tends to lower the blood velocity in the middle sized vessels and increase the blood pressure; but the increased frictional surface encountered in the middle sized arteries results in an actual lowering of the blood pressure.

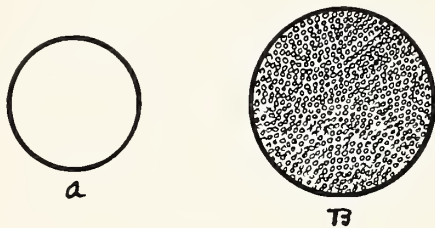

Fig. 8.

Figure 8, *A*, represents a cross section of the aorta and *B* the sum of the cross sections of the arterioles somewhat larger than *A*. Although the cross sectional area of the blood stream in the arterioles is greater than that of the aorta, the sum total of surface areas of the arterioles is much greater than that of the aorta, which results in a greatly increased frictional resistance. We know that the frictional resistance is proportional to the surface area in contact with the stream. While the cross sectional area of the capillaries is 600 to 800 times that of the aorta and the sum total of the surface area of the capillaries affording frictional resistance is enormously increased, on the other hand the great increase in the bed of the blood stream results in a marked slowing of the blood flow (to 1 mm. per second) and in the presence of such a slow velocity friction is relatively slight.

Both right and left ventricles eject blood by a shortening of the muscles, which decreases the size of the ventricles, thus forcing the blood into the pulmonary artery and the aorta. Their stroke volumes are equal and also of course their minute volumes (the blood ejected in a minute). The left ventricle propels blood into the aorta during systole, and the aorta is distended and its elasticity maintains arterial pressure during diastole. No diastolic pressure could be maintained in the arterial system were it not for peripheral resistance. This is supplied largely by the arterioles.

Assuming the muscular contraction of the ventricles to be isotonic, that is, that the rate of contraction is

the same throughout systole and that the ventricular cavity were the shape of a sphere and emptied completely during systole, much more blood would be expelled during early systole than during late systole.¹¹

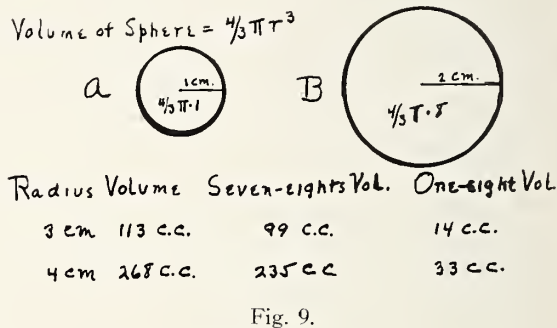

Figure 9 represents two spheres with radii of 1 and 2 cms., respectively. The volume of a sphere is $\frac{4}{3}\pi r^3$. The volume of sphere *A* with a radius of 1 cm. is $\frac{4}{3}\pi \times 1$, or about 4 c.c. A sphere with a radius of 2 cm. is $\frac{4}{3}\pi \times 8$, or about 32 c.c. Thus a sphere with twice the radius of another has a volume eight times as great. Thus if the ventricle were a sphere it would expel seven times as much blood during the first half of systole as during the last half, while its radius was being reduced by half, providing it completely emptied with each contraction. It seems warranted to assume that the heart expels at least seven-eighths of its content during the first half of systole. This relationship of eight times the volume in a sphere with twice the radius applies no matter what the size of the sphere and in cardiac dilation seven-eighths of the ventricular content may be a considerable volume of blood.

The great amount of blood ejected from the ventricle during the first part of systole largely distends the aorta and raises the intra-aortic pressure from its diastolic to its systolic level. This results because more blood enters the arterial system during this time than leaves through the capillaries. Much less blood being expelled by the ventricle during the latter half of systole and at a lesser rate than the blood leaves the arterial system, the intra-aortic pressure in late systole drops.

Fig. 10. Modified from Wiggers.

Pressure curves in the ventricle and subclavian artery (or aorta) are shown arranged synchronously in Figure 10, *A*.¹¹ As the ventricle begins to contract, the

intraventricular pressure rises to the point *b*, during which its contraction is isometric, that is, no actual shortening of the muscle fibers of the heart has occurred. As the intraventricular pressure arises above the diastolic pressure in the aorta, the pressure within the aorta begins to rise (1-4). The high point of pressure in both ventricle and aorta is reached at about mid-systole and both pressure curves descend during the latter part of systole. The aortic valve closes at 6, indicated by the dicrotic notch, when the intraventricular pressure *c* is only moderately higher than it was at the beginning of systole *b*. The result of this lower intra-aortic pressure at the end of systole is sparing to the aortic cusps.

As was stated, the blood pressure in the systemic circulation decreases progressively towards the periphery. In the aorta it varies between systolic and diastolic values. In the medium sized vessels² the mean pressure is about 20 mm. Hg. less than in the aorta and it falls some 50 to 60 mm. in the arterioles. In the capillaries it has been estimated at about 20 mm. Hg. and it falls progressively in the veins to about 5 mm. of water in the vena cava. The difference between diastolic and systolic pressures gradually becomes less as the periphery is approached and disappears in the capillaries and veins. The venous pressure in the upper portion of the body reaches zero in the lower jugular veins, beyond which it is negative, being -35 to -80 mm. of water at the right auricle during relaxation of the auricles.

Several factors assist the return of the blood through the veins to the right heart. Respiration is one. In the pleural space there is a negative pressure of about -6 mm. during inspiration which becomes about -2.5 mm. Hg. during expiration.² This negative pressure within the thorax is exerted on the vena cava and added to the slight positive pressure within the large veins produces return blood flow to the right auricle. The contraction of the diaphragm increases intra-abdominal pressure, which in turn exerts pressure on the inferior vena cava. The presence of valves in the inferior vena cava and in the iliac veins prevents the blood from returning to the periphery and thus periodic abdominal pressure assists in blood return to the right auricle. Muscular action in the lower extremities also aids venous flow in the extremities. The assistance to flow rendered by these several factors is greatly increased during exercise.

Variations in intrathoracic pressure affect the circulation. With the glottis and respiratory track open there is a negative pressure in the thoracic cavity during both inspiration and expiration due to the elasticity of the lungs. With the glottis closed, however, forced expiration (a grunt) may increase the intrathoracic pressure to 60 or 100 mm. Hg., which overcomes the negative pressure in the pleural space, and being much greater than the pressure in the inferior and superior vena cava, may prevent filling of the right auricle. If maintained long enough, it may produce syncope. This effect on venous pressure is evident if one watches an infant at stool. Its face becomes suffused with blood and the vessels in the neck become distended. On the other hand, forced inspiration with the glottis closed

causes a marked increase of 30 to 80 mm. Hg. in the negative pressure in the thorax. In asthma the assistance rendered return circulation by forced inspiration should about counteract the interference afforded by forced expiration. Perhaps this explains the absence of evidence of cardiac strain in many of these cases.

The velocity of the blood flow varies greatly in different regions of the circulatory field. It is greatest in the aorta during early systole, while it is zero at the root of the aorta during diastole. We have mentioned that as arteries branch off the aorta the blood bed is increased, which tends to reduce velocity. The bed of the stream is so large in the capillaries that the velocity there is minimal. Such a slow flow in the capillaries facilitates exchange between blood and tissues. In the veins the velocity increases as the heart is approached, being greatest in the superior and inferior venæ cavæ, although the velocity here is not as great as in the aorta as the combined cross sections of these large veins is greater than that of the aorta. The circulation time from right jugular to left jugular, which represents the shortest course from right jugular to right heart, lungs, left heart, head and left jugular has been determined to be twenty-three seconds.

A number of tests for determining the velocity of blood flow have been proposed for clinical use.¹ Five minims each of ether and normal saline are injected into the median basilic vein and the time it takes for the odor of ether to be noticeable to patient or observer is recorded. This measures the velocity of the blood stream from the vein to the lung. The time period varies in normals but four to eight seconds may be taken as the normal figure, an increase in this time indicating right heart failure. Similarly the velocity of the circulation from the median basilic vein to the tongue is determined by the injection of different substances. Saccharine produces a sweet taste, decholin a bitter taste, and calcium gluconate a sensation of heat in the throat. The time in normals is about eight to sixteen seconds and lengthening of the time indicates slowing of the circulation between these two points, due to a weak left ventricle or both left and right ventricles. The difference between the vein to tongue and the vein to lungs times would indicate the time taken from lungs to tongue and an increase above the normal would indicate an impaired left ventricle alone. Nausea and vomiting sometimes accompany the decholin test and an appreciable percentage of all the tests is accompanied by thrombosis of the vein. It is likely, however, that these tests are of value in certain cases.

The blood pressure in the pulmonary circulation is normally about 40 systolic and 12 diastolic, with a mean pressure of about 20 mm. Hg. Although the right ventricle pumps the same amount of blood as the left ventricle during the same period of time, its work is only about one-third that of the left, as most of the work of the ventricles is in overcoming resistance. The right ventricle has need therefore of a less powerful muscle.

Certain factors affecting the blood pressure in the popliteal artery are worth considering. Figure 11, *A*, shows a tube of uniform caliber through which fluid is

flowing at a uniform rate and tubes of smaller uniform caliber 1, 2 and 3 tapping the tube at different angles. Tube 2 is a piezometer tube and the pressure as indicated by the fluid level is unaffected by the velocity in the main tube. The fluid level in tube 1, however, is lower than in tube 2 and the level in tube 3 is higher than in tube 2, pressure due to velocity head being subtracted in tube 1 and added in tube 3 to the lateral pressures. Figure 11, *B*, shows schematically the vessels leaving the arch of the aorta at right angles and the bifurcation of the aorta into right and left iliacs. The angles at which the iliac arteries leave the aorta explain the higher blood pressure in them and in the popliteals than in the aorta and brachials even in the horizontal position. Pressure due to velocity is added to the lateral pressure in the popliteals.

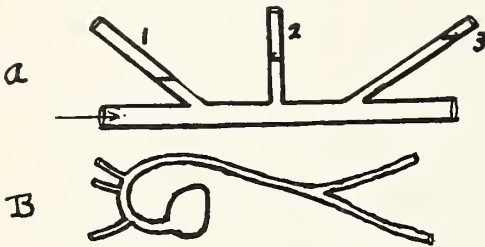

Fig. 11.

Hydrostatic factors have little effect on the circulation when the individual is in the horizontal position. In the erect position, however, it aids arterial flow in the lower extremities, increasing blood pressure in the popliteals. In this position it hinders return flow from the lower extremities to the heart to the extent of the pressure of a column of blood of about three and a half feet (77 mm. Hg.); in the upper extremities it assists arterial flow but hinders venous flow and in the head its action is the opposite. In one patient with normal circulation, the brachial blood pressure was 135-85 and that in the leg 168-108, both taken in the recumbent position. On standing, the blood pressure reading in the leg was 200-160.

The greater the viscosity of a fluid the greater the friction encountered in passing through tubes. Blood is five times as viscous as water and its viscosity is increased in polycythemia, leukemia and anhydremia. This increase, however, does not cause any significant deviation from normal in the circulation.

The total blood in circulation amounts to about five or six liters. In addition to the circulating blood there is an appreciable amount of blood lying passive or moving very slowly in the spleen, liver and so-called subcapillary spaces which is mobilized under certain conditions, such as during exercise and after eating.¹²

There is no uniformity of opinion as to the amount of blood pumped by each ventricle at each contraction (stroke volume) or as to the amount pumped in a minute (minute volume). Some³¹ state the stroke volume at rest is 50 to 60 c.c. This would amount to a minute volume of about 4,000 c.c. Some writers estimate that the heart is capable of varying its amplitude

of stroke, from three to ten fold. Henderson,¹³ on the contrary, states that, "Convincing evidence from a wide range of sources indicates that in vigorous men and other mammals of all sizes the stroke volume of the heart is a nearly constant quantity for each individual. Both during rest and work it is of the order of magnitude 1.5 to 2 c.c. per kilo body weight." According to this view the stroke volume would be 105 to 140 c.c. for a 154-pound man and 150 to 200 c.c. for a 220-pound man. According to these figures the minute output for a 154-pound man would vary from 7,350 to 9,800 c.c. at a pulse rate of seventy and from 10,500 to 14,000 for a 220-pound man with the same pulse rate of seventy.

During exercise³¹ the systolic blood pressure may be elevated to 160 or 180 mm. Hg. and the diastolic to about 120. The heart rate also increases during exercise, more in those accustomed to sedentary life than in athletes. A doubling of the heart rate would result in twice the heart output, providing the ventricle filled as completely during exercise as at rest. If the stroke volume is increased during exercise a doubling of the heart rate will more than double the minute volume. Best and Taylor state that the minute volume may increase from 9 to 37 liters during exercise. This cannot result from an increase in heart rate alone and presupposes a greater stroke volume during exercise. The duration of systole changes very little with increase of heart rate, but most of the rate increase is at the expense of diastole. Wiggers³¹ has shown that the minute volume increases proportionately with heart rate up to 60 to 78 per minute. With rates of 78 to 210, the minute volume steadily increases but not proportionately with the heart beat. This means that the stroke volume in rates from 78 to 210 is less than at rates below 78 and is contrary to the idea that the ventricle dilates during exercise. Beyond the rate of 210 the minute volume shows a decrease, as the ventricle does not have sufficient time during diastole to fill well. This occurs in paroxysmal tachycardia, a case having been reported in which the stroke volume was reduced from 70 to 12 c.c. Such a marked diminution in blood supply if prolonged may be serious. One case has come to my attention in which a heart rate of about 266 lasting two or three days in a six-months old infant was followed by a serious deafness, presumably due to prolonged undernutrition to the delicate auditory nerve fibers. In another case of a forty-three-year-old physician death occurred in about twelve hours from an attack of paroxysmal tachycardia because he insisted on actively caring for his patients.

It seems certain that the capacity of the ventricle varies in different normal individuals. The trained athlete doubtless has a larger ventricular capacity and a greater musculature than one unused to exercise. The minute volume is certainly increased greatly during exercise but probably not because of any greatly increased stroke volume. Certainly x-ray examination of hearts during exercise fail to indicate increase in diastolic volume. We have noted the marked effect increased rate and depth of respiration and muscular action in the lower extremities have in increasing the return flow

of blood to right heart. This results in a better supply of blood to the right heart and more rapid filling during diastole.

The term work is used in a special sense in physics. A man leaning against a wall to keep it from falling is not expending energy in work as the term is used in physics. Work in physics is the product of force expended by the distance it acts. The work of the heart is the force required to move a certain amount of blood times the distance moved and the work required to give the blood a certain velocity. It has been determined that the energy of the heart used in giving velocity to the blood amounts to less than one per cent of the total work of the heart. Therefore the velocity factor of the heart's work may be ignored in calculating roughly the work done. The force exerted by the heart at each stroke is the same as the peripheral resistance overcome. The heart expelling 100 c.c. of blood at each stroke through a tube 3 cm. in diameter will propel it 14 cm. The mean resistance encountered in the aorta is 97 mm. Hg or 132 cm. of water. If the heart were connected with a tube of water it would therefore at each contraction lift a column of water 132 cm. high and 7 sq. cm. in cross section a height of 14 cm. Such a column of water weighs 924 grams. Thus at each stroke the heart does about 13,000 gram-centimeters of .13 kg. meters of work. Each minute the work of the heart would be $.13 \times 80$ (pulse rate) or about 10 kg. meters. This is the equivalent of raising 10 liters of water 1 meter each minute. This applies to the left ventricle alone and as the work of the right heart is about a third of that of the left, the total work of the heart would be roughly raising 13 liters of water one meter each minute, the individual being at rest.

The caliber of the arteries is subject to variations and is controlled by the sympathetic nervous system. There is probably a vasodilator center as well as a vasoconstrictor center. With constant pressure head the velocity head is proportional to the sectional area of the tube but the quantity of fluid passing through the tube per unit of time (the volume flow) is proportional to the forth power of the diameter of the tube (Poiseuille's law). Slight changes in the caliber of the peripheral arteries therefore produce great variations in the volume of the blood flow. In addition to the vasodilator and the vasoconstrictor centers the carotid sinus doubtless plays an important part in regulating blood pressure and blood supply. Increase of blood pressure in the carotid sinus causes slowing of the heart and dilatation of the peripheral vessels, while decrease in pressure in the sinus causes acceleration of the heart and vasoconstriction.

Valvular heart disease is accompanied by changes in the hydrodynamics of the circulation. In mitral regurgitation of mild degree the left auricle and the pulmonary veins may care for the increased blood content during systole without causing an increase in intrapulmonary pressure. If hypertension is present as well as mitral regurgitation, a greater amount of blood will be regurgitated into the pulmonary circuit during systole, which may well cause pulmonary congestion. In mitral stenosis intrapulmonary pressure and blood volume are

increased and sclerotic change in the pulmonary vessels follows. In aortic stenosis systole is prolonged, intraventricular pressure systole is increased, the stroke volume is decreased, the velocity of the blood passing through the aortic valve is increased, while both systolic and diastolic pressures are lower than normal.

The hydrodynamic changes in circulation which occur in aortic regurgitation are marked and have been the subject of considerable study. It has been argued that little blood actually regurgitates in this valvular lesion. That this may be considerable, however, is proven by the greater capacity of the left ventricle compared with the right as found at autopsy, the difference in capacities indicating the leakage during life. Thus the stroke and minute volumes in the presence of this lesion may be greatly increased at rest and in the presence of a normal pulse rate. The diastolic blood pressure is characteristically low and by way of compensation the systolic pressure is increased. The resultant mean pressure, however, is below normal, which is given as the reason for the characteristic pallor in these patients. More blood than normal being expelled from the left ventricle during systole, the velocity of the blood in the arterial tree is much increased above normal during early systole. The systolic pressure in the popliteal arteries being affected by changes in velocity shows therefore a marked elevation above normal in the presence of this lesion. The velocity factor in the work of the heart is increased, and, according to Evans,⁸ may even exceed that in overcoming intra-aortic pressure. The increased velocity of the blood flow in the arteries in early systole, according to Gladstone,¹¹ accounts for a more rapid flow through the capillaries. Stewart had argued the presence of a reflex vasomotor dilatation to spare the heart in this condition. Vasomotor dilatation is not, however, in keeping with the pallor present with this lesion.

The capillary pulse is characteristic of aortic regurgitation. It indicates a high pulse pressure which is due to a much greater output of blood from the heart during early systole under an increased velocity, which suddenly fills the capillaries and a low diastolic pressure, due to the leak in the aortic valve. The decrease in intra-aortic pressure during late systole is abnormally great (Fig. 10, *B, c*), but the extreme low pressure in the presence of this lesion occurs during diastole and the blanching of the capillaries is probably due to the regurgitation. In the original curves by Wiggers the point *c* in figure *B* is not designated. Although stated to be abnormally low, it must be higher than *b*.

In the presence of both aortic regurgitation and stenosis, blood pressure readings are influenced by the degrees of leak and narrowing of the valve. A high pulse pressure is usually present, although one encounters some cases in which the pulse pressure is within normal limit, the explanation of which is not clear. However, if the stenosis is extreme, systole is prolonged and diastole, during which the leak occurs, is correspondingly shortened, intra-aortic pressure is lower than normal, the left ventricle does not completely empty and there is congestion in the left auricle with a more rapid filling of the ventricle in diastole—all of which tends to minimize the amount of blood regurgitated.

Circulatory failure is of two types—the so-called forward and backward types.¹⁴ The forward type is due to a diminished cardiac output with a diminished filling of the peripheral vessels. Circulatory competence depends on a distended arterial system. Diminished minute volume beyond a certain point results in failure of the circulation. This occurs in paroxysmal tachycardia, heart block and myocardial disease. It also occurs with any marked reduction in blood volume such as that following severe hemorrhage, secondary traumatic shock or severe burns. Decline in blood volume tends to produce a decline in venous pressure which results in less blood reaching the heart.

Backward failure is the more common type and is known clinically as decompensation with passive congestion. The failure may be due to the left heart or both left and right heart. The left ventricle or auricle or both become congested and there is pulmonary congestion with right heart failure, liver congestion and ascitis. Common causes are mitral stenosis and regurgitation, left ventricular failure in hypertension and aortic regurgitation.

Circulatory failure of neurogenic origin occurs in simple fainting from emotional causes, postural hypotension, knock-out blows and in primary shock following operation or wounds even without loss of blood. The manifestation is too sudden to be due to liberation of toxins or loss of blood plasma and can only be explained on a nervous mechanism. In this type of circulatory failure dilatation of the peripheral vessels results in a lowering of peripheral resistance and blood pressure. The venous pressure is low and less blood is returned to the heart. Assuming the horizontal position is important, and thus the hydrostatic interference of return circulation to the heart is overcome. This occurs spontaneously as the patient falls in fainting, but maintenance of upright position may prove fatal.

In secondary shock following operation or wounds, the shock occurs several hours after the injury and is characterized by pallor, cold sweating, fall in temperature and blood pressure and a small rapid pulse.¹⁴ It has been shown that an oligemia exists due to a leakage of plasma from the blood into the tissues and the great veins are depleted. The blood shows a high hemoglobin and red cell count. According to recent work this loss of blood plasma is probably due to a dilatation of the capillaries produced by an liberated toxic substance resembling histadine. Several theories as to its causation have been advanced, but as yet no final answer as to the exact mechanism involved can be given. Treatment consists in rapid addition of fluid to the depleted blood volume.

Simple fainting is common. It occurs at times in young women with feeble musculature on standing for the dressmaker or when soldiers, not necessarily with poor musculature, stand long at attention. It is due to a cerebral anemia which in turn is due to an insufficient venous return to the heart. The hydrostatic pressure exerted in the venous system leading from the lower extremities is opposed to the comparatively low pressure within these veins. This interference with circulation by the force of gravity is well known in the case

of the rabbit, which, used to the horizontal position, may die if held in the vertical position too long. The rabbit lacks the vasoconstrictor mechanism necessary for adjustment in the upright position. On fainting, the individual automatically assumes the horizontal position and the blood again reaches the heart. It might be serious if the upright position were forcibly maintained. It is questionable whether locking the knees, namely, hyperextension of the knee joints, tends to cause fainting by excessive pressure on the popliteal veins. Voluntary deep respiration and grunting should aid in preventing fainting.

Some individuals faint easily and of course the blood pressure falls at such times. There is, however, a severe form of hypotension and syncope associated with the assumption of the erect posture which is comparatively rare and quite different from mere fainting.⁷ This is characterized by syncope and hypotension and a slow and unchanging pulse on standing, thus indicating a disturbance in the adjustments normally made through the sympathetic system to changes in position. The condition is often associated with other evidence of neurological disease. Blood is pooled in the dependent vessels and circulatory failure of the forward type occurs. Ephedrin and abdominal binders help in some cases.

In hypertension the work of the heart may be increased 40 to 50 per cent at rest. That is why the marked increase in work of the heart accompanying strenuous exercise should be avoided. The stroke and minute volumes are generally normal in amount.²⁹ As a narrowed arteriolar bed is present and the same amount of blood circulates, its velocity must be increased in the arterioles. This increase in velocity is accompanied by an increase in resistance. Any attempt at therapy aside from avoiding strenuous exercise should be directed at overcoming the arteriolar resistance rather than attempting to lessen the force of the heart action.

In arteriosclerosis of the larger arteries, hydrodynamics of the circulation tends to approach that encountered in rigid tubes. The blood in the aorta in early systole is less taken care of by the diminished elasticity of the aorta and the pressure transmitted to the aorta is more directly applied through the column of liquid to the periphery. The velocity of the pulse wave we know is increased. The pressure during diastole is less well sustained and is consequently lower. The systolic pressure we would expect to be higher by way of compensation. More of the work of the heart is expended in kinetic energy.

The effect of arteriosclerosis involving the large vessels on blood pressure is not at all clear. We see elderly individuals with evidence of considerable change in their vessels and little change in their blood pressures. On the other hand, it is difficult to explain blood pressure reading of 210-90 or 160-60 in elderly individuals on a basis of arteriolar change and I am inclined to attribute such a reading to sclerosis of the large vessels, although Weiss does not concur in this interpretation.

In coarctation of the aorta we have a narrowing of the aorta with local increase in the velocity and lowered pressure. Beyond the constriction the velocity becomes less and the pressure greater, but still below normal level. The heart compensates to overcome the increased resistance by hypertrophy and the pressure proximal to the constriction is increased. Increase in collateral circulation provides for a return of the blood volume which cannot take its normal course because of the narrowed aorta.

In adhesive pericarditis there is a mechanical interference with the normal hydrodynamics of the circulation. Adhesions to surrounding structures necessitates greater muscular work on the part of the heart. As adhesive pericarditis is often associated with valvular leakage there is in these cases need of dilatation as well as hypertrophy. If the thickened and often calcified pericardium prevents the required dilatation, the circulation is handicapped even with the patient at rest. If the right ventricle cannot fill sufficiently during diastole, there is back pressure and the characteristic ascites. Less blood expelled by the right heart results in less blood reaching the left ventricle and a reduced supply to the systemic circulation. The brilliant results from surgical removal of the constricting pericardium are obtained by permitting adequate diastolic filling of the heart. An important point in connection with the operation is the necessity of relieving the constriction of the left ventricle before the right. If the right ventricle is relieved first, its filling, and hence stroke volume, become greater than the left ventricle can accommodate, which may result in fatal pulmonary congestion.

In the presence of pericarditis with effusion it is readily understandable how a rapid accumulation of fluid in the pericardial sac can easily be fatal by preventing normal filling of the heart chambers. The pericardium is known to be quite resistant to acute distention. In filling, the muscles of the heart chambers exert no active suction on the blood in the large veins but filling is dependent on the low pressure in the large veins plus the negative intrathoracic pressure exerted on the heart itself.

The presence of a patent ductus arteriosus produces a disturbance in pressures. The mean blood pressure in the aorta being normally about four times that in the pulmonary artery and the aortic pressure being transmitted to the pulmonary artery throughout systole and diastole, the pressure and the volume of the blood to the lungs is greatly increased above normal, thus increasing work of the right ventricle. The right ventricle hypertrophies and dilates. Ligation of the patent ductus has proven comparatively simple and very successful in operations recently reported.

In arteriovenous fistula the arterial blood stream flows into a vein, the pressure of which is much less than that in the arterioles. Thus peripheral resistance is less²¹ and the heart shows marked hypertrophy and dilatation in most cases, the diastolic pressure is lower, and the systolic higher than normal by way of compensation. Operation results in a return of heart and blood pressure to normal.

The blood pressure in the pulmonary circuit in man is estimated at about 40 systolic and 12 diastolic. Increase in the pulmonary blood pressure is, according to Moschowitz,²² almost always a secondary process and is accompanied by arteriosclerosis of the pulmonary arteries. It occurs with any lesion in the left heart which results in back pressure in the lungs. Mitral stenosis is a common cause and in severe cases the entire lung field shows on x-ray increase in lung design from blood vessel thickening. The independence of arteriosclerosis of the systemic and pulmonary circulations indicates, according to Moschowitz, that the cause of arteriosclerosis is not toxic, metabolic nor dietary.

The fall in blood pressure encountered in spinal anesthesia is caused by the cutting off of the vasoconstrictor action of the sympathetics on the blood vessels. While there are believed to be both vasoconstrictor and vasodilator nerves to the arteries with respective centers in the brain, there is some question as to the mode of action of the dilator nerves, that is, whether it is an active process or not. Section of a nerve trunk containing both kinds of fibers and stimulation of the peripheral segment results in arterial constriction which shows a greater action on the part of the constrictor fibers. This explains the dilating action on putting the sympathetic fibers out of commission by spinal anesthesia. The splanchnic and leg vessels in spinal anesthesia become dilated and peripheral resistance is lowered, which results in a lowering of blood pressure and increased pulse rate, and if the dilated vessels acquire too much of the circulating blood, the venous return to the heart is diminished. In hemorrhage there is a prompt compensatory vasoconstriction which tends to maintain blood pressure. This is impossible in spinal anesthesia and therefore this form of anesthesia is contraindicated following hemorrhage or in operations likely to be accompanied by considerable loss of blood. The importance of the horizontal position in spinal anesthesia is apparent. Ephedrine acting on the unaffected vessels tends to minimize the lowering of blood pressure in these cases.

The application of some of the laws of hydrodynamics to normal circulation and to a number of abnormal conditions encountered clinically has been attempted in an effort to make the subject of circulation more intelligible and therefore more interesting.

For valuable assistance I am indebted to Mr. Russel F. Varney, master at the Saint Paul Academy.

Discussion

DR. S. MARX WHITE, Minneapolis: This presentation ought not to go without discussion. I do not consider myself capable of discussing the details of this paper but I am interested in this fact that, as medicine grows and our knowledge in medicine increases, increasingly we are interested in physiology. It is true that the physiologist has been able to add very greatly to our knowledge. Physiology is one of the fundamentals in the science of medicine. Everything that Dr. Drake has presented has been of extraordinary value. He had not the time to go into other fields of hemodynamics, such as those that may play a part in fluid interchange through the vessel walls. A difficulty in all of this is that we are facing a complexity of the forces with which we deal. While he was discussing the forces in hypertension and hypotension, my mind went back to a couple of incidents that impressed it on my mind. We have been taught that in aortic stenosis there is, as a rule, much less sclerosis in the proximal portion of the aorta than is commonly found in the same age group. A patient of fifty-five years whom I had watched for several years had had an attack of rheumatic fever at the age of eighteen, none since. At autopsy, marked sclerosis was found in this vessel. Some other factor, possibly hereditary, had stepped in to modify the picture.

I did not hear Dr. Lepak's paper on hypotension at the last meeting, but I have in mind a man whom I

had studied for ten years. We found marked static hypotension to systolic pressures of 70 mm. of mercury and even lower. At no time did we find blood pressures over 135 systolic or 90 diastolic. We overcame the spells of fainting which the man had while shaving in the morning and which had been looked upon previously as mild epileptiform seizures. This was corrected largely by an abdominal belt designed to prevent over-distention of abdominal veins. This man died on the sixth day of his first attack of coronary occlusion. We found he had a heart markedly increased in weight. I don't introduce these to confuse the picture; I do it in order to bring our attention back to the fact that in the work of the physician and surgeon we are dealing with a multiplicity of forces in which many things come into the picture.

DR. MOSES BARRON, Minneapolis: The study of hydrodynamics in heart disease has assumed importance in recent years and has helped clarify many phases of congestive heart failure. It has now been fairly well established that congestive heart failure is best explained by the back pressure theory. The old concept of the forward failure theory has been abandoned. A patient with advanced heart failure from any cause, whether from hypertension, coronary disease, valvular disease or any other etiological factor, presents increased venous pressure. The minute volume cardiac output is often normal until an extreme state of heart failure develops and at times may be normal even then. There are only a few conditions affecting the heart which would produce definitely a diminished minute volume output. The two important ones are: (1) constrictive pericarditis, when an insufficient amount of blood reaches the heart because of the inability of the blood chambers to receive the normal amount; and (2) when there is tricuspid stenosis present, a condition which also results in inflow stasis. These heart conditions result in forward failure, otherwise forward failure comes when there is peripheral vascular collapse, a condition found in severe shock. A loss of tone of the blood vessels results in increased vascular bed, but especially an escape of fluid through the capillary endothelium with a diminished return flow of blood to the heart. It is important that we recognize these two distinct types of circulatory insufficiency, the one due to cardiac weakness and that due to peripheral vascular collapse. The treatment of the two conditions is altogether different. In the first, cardiac stimulants are indicated; while in the second the attempt should be made to increase the vascular tone and supply more fluid to the circulating system.

Another interesting point brought out by Dr. Drake is the inconstancy of the blood pressure associated with arterial sclerosis. If the sclerosis involves the larger vessels without affecting the pre-capillary arterioles, there may be no increase in the systolic pressure. If there is a high systolic pressure associated with the low diastolic, it may signify that there is sclerosis of the larger blood vessels which has eliminated the elasticity and prevents the vessel wall from contracting down upon the circulating blood. This lack of contraction explains the low diastolic pressure. In cases of aortic regurgitation the low diastolic associated with a high pulse pressure is probably not the result of the amount of blood regurgitating into the ventricle but rather of some reflex dilation of the peripheral vessels. The thrust of blood at systole into relaxed blood vessel walls explains the loud pistol shot tone so often elicited in cases of aortic regurgitation.

DR. DRAKE, in closing: I wish to thank Dr. White and Dr. Barron for their discussions. Dr. Barron's explanation of the reason for the comparatively low diastolic pressure readings in some cases of hypertension with arteriosclerosis is particularly interesting.

The meeting adjourned.

A. G. SCHULZE, M.D., *Secretary*

TRANSACTIONS of the MINNEAPOLIS SURGICAL SOCIETY

Stated Meeting, Thursday, November 2, 1939

President, Dr. Willard White, in the Chair

Secretary, Dr. Harvey Nelson

THE SURGERY OF PEPTIC ULCER

MARTIN NORDLAND, M.D.

Minneapolis

The conception that a peptic ulcer is an acute process healing rapidly and spontaneously and that each attack of symptoms is due to a new ulcer has been widely accepted. The surgical treatment of peptic ulcer is indicated only for complications, namely, perforation, gross hemorrhage, pain intractable to medical management, pyloric obstruction which is not amenable to medical management, and gastric ulcers questionably malignant. All of these complications, with the exception of perforation, may be favorably affected by dietary measures.

While the total number of cases requiring surgery does not vary, the number of patients operated upon for different indications has been greatly modified. Surgical interference for the so-called intractable pain has diminished 50 per cent, while the number of patients operated on for massive bleeding has increased markedly in recent years. Gastro-enterostomy, which still has its place in the selected case, is no longer employed as a routine procedure. The pyloroplasty of Finney and the gastroduodenostomy of Wilken have been found to have many disadvantages. At the present time the trend is to direct efforts toward selective surgery, the responsibility of the surgeon being to select the patient for the operation and not the operation for the patient.

Twenty years ago Finsterer suggested early operation as a treatment of choice for hemorrhage from chronic ulcer because, as he contended, such hemorrhage coming from an eroded large artery at the base of a penetrating ulcer could be stopped permanently only in this way. Foreign surgeons rapidly accepted his point of view and generally adopted surgical intervention in the treatment of bleeding ulcer. In this country, Lahey is conspicuous in joining Finsterer in the adoption of the more radical procedure, such as sub-total gastrectomy for hemorrhage, as well as for the gastric ulcer in which the question of malignancy cannot be settled, and other complications. Lahey contends it is being more and more accepted that conservative surgical procedures, such as gastro-enterostomy and pyloroplasty, are no longer justifiable as routine operations for patients with gastric and duodenal ulcers. The too frequent postoperative occurrence of gastrojejunal ulcer is so resistant to medical management, has caused a great many surgeons to avoid the routine use of these conservative operations.

Acute perforation always requires surgical interference. A few small ulcers are walled off spon-

taneously by the omentum or a neighboring viscus. These patients may survive without operation. Naegeli (*Surgery*, November, 1938) reports a case in which a patient with acute perforated gastric ulcer of forty hours' standing was successfully treated with nasal suction. This procedure undoubtedly has value in the late cases. He calls attention to a disadvantage, that is, the depletion of Vitamin B radical through continuous emptying of the stomach. Evidence of this depletion was shown by the precipitation of a marked bradycardia and the improvement of the patient by the hypodermic introduction of Vitamin B. The mortality in cases with acute perforation is in direct relation to the length of time that has elapsed between the onset of the attack and the operation. Kelly (*Surgery*, October, 1939) comments that men are more prone to perforated ulcer than women, perforations occur more frequently during the middle years of life, the mortality increases with the age of the patient, and that the majority of perforations have antecedent histories of gastric disturbance and the physical findings are fairly constant, enabling an early diagnosis. Roentgenography is an aid in establishing the diagnosis in doubtful cases. The surgery in nearly every case need include no more than simple closure of the perforation. The procedures other than simple closure are used to cure the ulcer and such operations performed under more favorable circumstances carry a mortality in themselves. Simple closure may be done by placing sutures in normal tissue on either side of the ulcer in such a manner that constriction is avoided, and tying them together. If this method is impossible because of the size of the ulcer, it is necessary to use an omental tab to cover the perforation, holding it in there by loosely tied sutures passed through the edges of the ulcer. Constriction of the duodenum rarely occurs when this is done. In any event, it must be recognized that while the pylorus may seem to be obstructed, most of the swelling is due to edema. This simple procedure is usually all that is necessary since it must be remembered that many patients are cured by the fibrosis of the ulcer which follows perforation and suture (Lehman). Whether or not the abdominal cavity is drained apparently makes no difference. The mortality rate is practically the same. Kelly feels that spinal anesthesia is the anesthetic of choice. Pulmonary diseases constitute the largest group of complications if peritonitis is excluded.

Massive and repeated hemorrhages are a distinct indication for surgical intervention. Finsterer contends that the main purpose of operative treatment in the presence of acute gastric hemorrhage is reliable hemostasis, the question of a permanent cure of the ulcer being of secondary importance. For the purpose of hemostasis, a gastroenterostomy is made. In cases of bleeding duodenal ulcer, the same operative pro-

cedure is performed combined with ligation of the pylorus. The gastroenterostomy helps only indirectly to control the hemorrhage. The continuous emptying helps the permanent contraction of the stomach. Finsterer states that in gastric ulcer penetrating to the pancreas, it depends on the general condition of the patient whether the margins of the ulcer are simply excised and the stomach is sutured or a typical gastric resection is performed. If a duodenal ulcer penetrating into the pancreas is not resectable on account of its position and extent, he does not perform resection for exclusion of the ulcer but substitutes for it a simple ligation of the pylorus combined with a posterior gastroenterostomy. Excision of the bleeding gastric ulcer, he states, can always be performed and has a perfect hemostatic effect. If, however, the condition of the patient allows it, instead of excision he performs a typical gastric resection which guarantees a permanent cure. Lahey states that while he is entirely in sympathy with the selection of sub-total gastrectomy as a method of choice in the surgical treatment of duodenal and gastric ulcer, nevertheless he thinks that occasionally cases will arise in which it would be unsafe and unwise to apply total gastrectomy. It would be a mistake, he believes, for any one dealing with gastric and duodenal ulcer to take the attitude that all patients with gastric and duodenal ulcer, regardless of their age, condition, weight, or location of the ulcer, should be submitted to a sub-total gastrectomy. He believes that in bad risk cases it is better to perform an operation with which one is not as well satisfied but to which is attached a lower mortality rate. He states that from his experience occasionally there are patients with indurated ulcers low in the duodenum close to and even involving the common bile duct, with a marked degree of pyloric obstruction, in whom sub-total gastrectomy cannot be done with safety because of the fact that there would be insufficient duodenum left for the safe inversion of its end. Lahey states, however, that every patient with ulcer who is approached surgically should be considered as to the possibility of sub-total gastrectomy and estimated upon the basis of his general condition, age, weight, and location of the ulcer, and then only should operative procedure be selected. Allen and Welch conclude, from a study of 2,700 cases at the Massachusetts General Hospital, that one massive hemorrhage is an indication for operation in patients over 50; a single hemorrhage in the younger group demands a careful medical régime. If the ulcer symptoms persist, or if a second massive hemorrhage occurs, operation is indicated. They state that the type of operation to be employed depends on the presence or absence of acute bleeding. Allen states that, in dealing with acute massive hemorrhage, the bleeding is controlled by the finger while all the vessels leading into the ulcer are ligated in normal tissues. If the operation is performed after the subsidence of the acute hemorrhage, a sub-total resection of the stomach should be done. If possible, the ulcer should be resected; if not, vessels supplying it should be ligated. He has found that the earlier procedure of

gastroenterostomy for massive bleeding has been found to be unsatisfactory.

Pain intractable to medical treatment in ulcer, or ulcer which cannot be differentiated from cancer, is an indication for surgical treatment. Although medical treatment of peptic ulcer is much more satisfactory than it was formerly, a certain number of patients still fail to respond. Some have persistent pain despite the fact that they are supervised carefully in the hospital. Others improve in a hospital, but, owing to excessive business worries or unhappy home environments, have a recurrence of symptoms soon after leaving the hospital. Many find it difficult to continue proper medical diet and have repeated re-admissions to the hospital. This is particularly true of an ulcer situated on the posterior wall and which through protective perforation has invaded the pancreas. Hunt states that it is not the gastric ulcer, complicated by perforations, continued bleeding, or recurrent massive hemorrhage, or persistent gastric retention in which the difference of opinion exists as to what the management shall be. It is the crater lesions with none of these complications in which there is a lack of unanimity of opinion as to what the appropriate treatment shall be. The question that arises here is: is it a benign ulcer or a carcinoma? In many instances the clinical, roentgenological and gastroscopic findings in a gastric lesion leave considerable doubt as to just what the nature of the lesion may be. Even with the abdomen open and with the lesion in his hand, the surgeon of experience has felt uncertain as to whether it is benign or malignant. Often this can be determined only by the pathologist. While lesions with a crater of less than 2.5 centimeters in diameter are usually considered benign and lesions of a greater diameter are considered malignant, nevertheless there are many exceptions to this rule. The only procedure that is rational in these cases is sub-total gastrectomy, according to most surgeons. In those cases in which it is impossible because of technical difficulties, to resect the stomach, Finsterer's "resection for occlusion" may be employed (Gorgas).

There is a large group of patients with pyloric obstruction or stenosis, due to the formation of dense scar tissue, who are not favorably affected by dietary methods and to whom the administration of antispasmodics brings no relief. This condition may develop in young patients, but is much commoner in older ones. If operation cannot be avoided and there is excessive reaction around the duodenum, a conservative operation such as gastroduodenostomy may be done, in hope that a later total gastrectomy may be safely done. In these cases there is usually a low gastric acidity. Complete relief from symptoms in this group is usually gained through gastroenterostomy and, when properly performed, there is no danger of the postoperative gastrojejunal ulcer.

Trimble (*Johns Hopkins Bulletin*, 1936) states that it is unfortunate that the term "vicious circle" was introduced into the surgical vocabulary for it gives an incorrect idea of the nature of the cause of some

vomiting that occurs postoperatively. He states that the so-called vicious circle is nothing but high intestinal obstruction and concludes that this high intestinal obstruction is a change in the mesocolon, usually from edema, which produces the obstruction. Such an obstruction would not occur, he thinks, if the mesocolon is sutured high up on the stomach so that from one and a half to two inches of stomach projects into the greater peritoneal cavity. He feels that if the mesocolon is sutured close to the line of anastomosis on the small intestine such a change in the mesocolon will certainly cause obstruction. While the short loop suggested by Peterson obviates some of the causes of obstruction, nevertheless Trimble is certain that suturing of the mesocolon high on the stomach is one of the principal factors in preventing high intestinal obstruction.

In stenosis there are factors other than technical errors which may cause complications in gastroenterostomy. The patient may present himself in a condition in which immediate operation would be extremely risky. There may be acidosis, alkalosis, or hypochloremia, and the general bodily nutrition may be at a low ebb. The stomach wall is usually so stretched by over-distention with food that it is difficult to estimate the required size of the gastroenterostomy stoma. And its muscular tone is so poor that after operation peristalsis is delayed and weak, accounting for many of the poor results. The intestinal tract distal to the obstruction, having become accustomed to little if any reception of stomach contents, becomes sluggish and atonic, its secretions are diminished, and a sudden influx of food after a gastroenterostomy will usually produce symptoms popularly classified under the heading of gases, but really due to definite motor and secretory disturbances.

Before any surgery is attempted, a careful pre-operative management should be employed, decompression of the stomach instituted to restore it as well as possible to its normal size. Many times this is very difficult. The advent of the nasal suction has assisted much in this procedure. Because of the jejunal ulcer and other complications following posterior gastroenterostomy, many surgeons have abandoned the posterior operation in favor of the anterior gastroenterostomy. In a discussion concerning the technical problems of gastroenterostomy, Dr. Arnold Schwyzer states that the stoma in the posterior gastroenterostomy is constantly bathed in the gastric juice when the patient is in the reclining position, which he thinks might account for ulceration at this point; while in the anterior gastroenterostomy, with the normal presence of gas in the stomach, the stoma is always free from the gastric juice when the patient is in the reclining position. He has abandoned the entero-anastomosis customarily performed in the anterior gastroenterostomy by fixing the afferent loop of the jejunum to the stomach for some distance beyond the stoma, increasing the width of the anterior Lembert suture as it advances beyond this point, thereby making the opening into the afferent loop much smaller and higher than the opening to the distal loop. Schwyzer further points out that a redundant mucosa at the

stoma protects the tissues against secondary ulcer on the suture line, and, for this reason, he prefers to secure a bulky covering by pulling ample mucosa over the wound. To assist in the retention of an ample mucosa, he does not stress the careful inversion of the mucosa when the anterior half of this suture is placed. If the edges are somewhat everted, he states, the suture does not look as neat but seen from the inside there is no exposed submucosa.

When gastroenterostomy is performed on a stomach that still retains much of its dilatation, the surgeon is confronted with a difficult mechanical problem. Here, it is most important to leave the pre-operatively introduced nasal catheter in place during the operation. Before the gastroenterostomy is completed, the catheter is pushed about 20 centimeters into the distal loop of the jejunum. Besides serving as a method for feeding in the dehydrated and emaciated patient, this maneuver acts as a "splint" for the anastomosis between the bowel and the stomach. This maneuver is a modification of "transgastric jejunal feeding" introduced by Dr. Arnold Schwyzer. It is a good mechanical procedure for all gastroenterostomies, but of particular value in "splinting" the anastomosis when dealing with a dilated stomach. We have made use of the pre-operative introduction of the nasal suction tube in all of our gastric surgery, leaving the catheter in position during the operation.

Summary

It is generally agreed that the indications for the surgical treatment of peptic ulcer are limited to the complications. The operative procedures employed for the treatment of complications are more carefully selected.

Gastroenterostomy is still the operation of choice in the treatment of chronic pyloric obstruction due to ulcer. The other conservative surgical procedures have little value.

The radical attack, to control massive hemorrhage from the eroded vessel in the older patient, is accepted as the better method; while the conservative management for repeated smaller hemorrhages in the younger individual, is thought to be more desirable.

Gastric resection for peptic ulcer in the selected patient, as recommended by Finsterer, is being more commonly employed.

All patients operated upon for complications of peptic ulcer should have strict postoperative supervision by a good internist.

Discussion

DR. R. R. CRANMER: Dr. Nordland has given us the indications for surgery in duodenal ulcer. Obstruction, stenosis, perforation, repeated massive hemorrhages, and patients who have received proper medical treatment over a long period of time who do not respond to that treatment, are those that should be operated upon. I think that one can add another group to that. The group that I refer to is made up of individuals, who, because of their financial status are unable to continue a long treatment; who cannot afford hospitalization, and who require more summary treatment than the medical treatment.

The percentage of duodenal ulcer cases that come to operation seems to vary in the larger clinics. Some

state that about 8 per cent of the cases they see are eventually operated. Others report as high as 40 per cent that eventually come to operation. I think Lahey operates on about 8 per cent of his cases. Now, we have all seen a variety of operations done for this over a period of years. Fifteen or twenty years ago, the operation of simple excision of the ulcer—a longitudinal incision with transverse closure, the so-called Heineke-Mikulicz operation was done frequently, and then followed various types of pyloroplastic operations. Finney's pyloroplasty and Judd's partial pylorotomy and Horsely's pyloroplasty, which he calls a physiologic pyloroplasty, are all, of course, really gastroduodenostomies. They are, of course, used by many surgeons today. But posterior gastroenterostomy has been the operation that has been used most frequently and which probably now is more frequently done than the other operation for this condition. However, the trend today is toward a more radical operation in this class of cases. The continental surgeons have for many years done the sub-total gastrectomy for duodenal ulcer. That was not accepted in this country, nor in England, until quite recently. We did have two men here, however, who started to do that several years ago—Strauss in Chicago and Berg at Mt. Sinai, New York. They were about the only two men who used that operation for this condition, and a lot of criticism was directed toward them for using such a radical operation. I remember attending a Clinic at Michael Reiss Hospital in Chicago when Strauss was doing this operation and Lahey happened to be there. When Strauss saw Lahey, he asked him to get up and tell what he thought about the treatment of that particular case—what he would do for that case. Lahey was hesitant about getting up and saying anything, but he finally did get up and indicated in a few words that he was not yet converted to the idea of removing half of a good stomach for the cure of an ulcer in the duodenum. However, as you know now, Lahey has been converted to that idea, as he has reported very recently a large series of cases—200 done previous to a year ago. The trend then has been away from these less radical operations toward the more radical ones, the reason being, of course, that the mortality rate in good hands is less when you consider that each one of the operations that were done carried a certain mortality and very often the patient had to be operated on several times.

Lahey, in speaking about the anesthetic, said that he first used ether, but has given it up. Then he used intratracheal ethylene and has given that up. He then used spinal anesthesia (novocaine crystals) but gave that up because of the shortness of the anesthesia. However, he now is back using spinal anesthesia. He uses a very dilute solution of Nupercaine, a one to sixteen hundred solution. That produces an anesthesia of about three hours duration.

What he does is the Hoffmeister operation, which, you know, is a modification of the Billroth No. 2 operation. The connection between the jejunum and the stomach is made near the greater curvature, and the rest of the stomach closed, but the jejunum sutured to the entire stump of the stomach, in order to stabilize it and prevent it from pulling away. He removes about two-thirds or three-fourths of the stomach in this operation, and his mortality rate, previous to two and a half years ago, was about 18 per cent. His mortality rate from two and a half years ago to one and a half years ago, was about 11 per cent, and he now has operated on fifty-one consecutive cases without any mortality.

Dr. Nordland spoke about Finsterer's exclusion operation which Lahey sometimes does. Some of those cases in which it is impossible to tie off the duodenum and invert it below the pylorus, he cuts the stomach just above the pylorus and inverts the edges of the stomach. He makes certain, however, in those cases

that there is not an obstruction of the duodenum, because the accumulation of the secretion manufactured by that small part of the stomach must get out; if it does not, rupture of the suture line is apt to occur.

THE SURGICAL MANAGEMENT OF CARCINOMA OF THE STOMACH*

OWEN H. WANGENSTEEN, M.D.

Minneapolis

At the January meeting of this Society in 1936, now almost four years ago, I reviewed my experience with the surgery of carcinoma of the stomach. I propose to review tonight the cases operated upon by me for carcinoma of the stomach during the intervening years. As a prelude to this discussion, I might add that during the past year there have been some notable contributions to the surgical literature of carcinoma of the stomach. Prominent amongst these is the distinctly unusual book of Livingston and Pack entitled "End-Results in the Treatment of Gastric Cancer." This book presents a detailed statistical analysis of the incidence and results of operative treatment of cancer of the stomach. Without question, it is one of the most informative treatises ever written upon the subject. There is also the splendid treatise of Konjetzny of Hamburg "Der Magenkrebs." This monograph deals essentially with the pathological aspects of carcinoma of the stomach, especially the relationship of gastritis to the development of carcinoma. And then there are two papers, one by Ogilvie of London and the other by Parsons and Welch of Boston. Perusal of these four references will afford satisfactory orientation on the best present-day thoughts concerning the surgical management of carcinoma of the stomach.

The experience reported by me, here, in 1936 represented cases of carcinoma of the stomach observed at the University Hospital in the thirty month period between July 1, 1933, and January 1, 1936.¹ During that period 109 cases of carcinoma were observed at the hospital. Of that group forty-four were inoperable on admission because of distant metastases or a general condition which would not allow operation. Of that group of forty-four, twelve or 27 per cent were terminal on admission and died in the hospital. Resection was done in thirty-one cases or 28.4 per cent of the entire group. Thirteen of the resections were done by me, amongst which number there was one death, a mortality of 7.6 per cent.

Results in the Present Group

The present study covers the period from January 1, 1936, up to the present time and relates only to the patients operated upon by me during this interval of time. In all, fifty-five patients were operated upon by me for carcinoma of the stomach. Exploration alone was done in eight instances with no deaths; in eight instances gastroenterostomy was done with one death; gastric resection was done thirty-nine times with eight deaths—a mortality rate for the resection group of

*From the Department of Surgery, University of Minnesota Medical School, Minneapolis.

20.5 per cent, a distinct increase of risk as contrasted with the smaller group operated upon in the preceding thirty month interval. The incidence of resection, however, amongst the patients operated upon by me in the present group was 70.9 per cent. Undoubtedly the indications for operation were stretched in a number of cases beyond the generally accepted orthodox indications for resection, as the subtended protocols of the operative failures will indicate:

Case 1. 1/22/36—Mr. J. E., U.H. No. 644903, age seventy-four years: Subtotal gastric resection; open anastomosis. Patient died 10 days after operation. Patient eviscerated on the fifth day. Small abscess at the site of the duodenal inversion and another at the upper end of the stoma. Evisceration undoubtedly had something, however, to do with the peritonitis.

Case 2. 4/29/36—Mrs. H. G., U.H. No. 647846, age sixty years: Extensive gastric resection for carcinoma, excising five-sixths of the stomach. Open anastomosis. Also large incisional hernia. Patient died 10 days after operation. Small abscess at the duodenal stump. Anastomosis intact. Contributing cause of death, pneumonia. Autopsy showed some coronary sclerosis.

Case 3. 12/2/36—Mr. C. B., U.H. No. 753763, age fifty-seven years: Carcinoma involving the distal three-fourths of the stomach; open anastomosis. Patient also had mild heart failure. Cause of death, gangrene of upper loop of jejunum due to torsion of loop. No enteroanastomosis had been made. Fatty degeneration of the liver and general peritonitis. Patient died four days after operation.

Case 4. 3/16/37—Mrs. C. P., U.H. No. 656619, age sixty-six years: Patient with extensive carcinoma of the stomach, adherent and fused to the pancreas. Open anastomosis, excising the greater portion of the stomach. Operative injury of the mesenteric vessels due to failure to define plane of cleavage between the pancreas and the carcinoma. Patient died three days after operation and hemoperitoneum from injury of the mesenteric vessels was found. Anastomosis was intact.

Case 5. 4/29/37—Mr. J. J., U. H. No. 652204, age seventy-three years: Extensive gastric resection, removing three-fourths of the stomach; open anastomosis. Patient could not void after operation and indwelling catheter had to be inserted. Patient died four days after operation of uremia, pulmonary edema and pneumonia. Anastomosis was intact.

Case 6. 1/5/38—Mr. M. N., U.H. No. 664896, age fifty-four years: Excision of distal two-thirds of the stomach for a very high carcinoma. Patient developed pneumococcus type II pneumonia with bacteremia. Treated by serum. Patient died three days after operation. Anastomosis intact.

Case 7. 2/6/39—Mrs. M. G., U.H. No. 675856, age sixty-two years: Patient had diabetes with a good deal of obstruction. Aseptic resection of the distal half of the stomach. Patient died 48 hours after operation of hypoglycemia due to administration of too much insulin. Small pulmonary embolus was found at autopsy.

Case 8. 2/24/39—Mr. E. G., U.H. No. 675913, age fifty-five years: Story of abdominal pain for about 10 months with a 20 pound weight loss. Considerable loss of strength. No vomiting. X-ray examination

showed a huge gastric defect which because of its size was interpreted as being possibly a lymphosarcoma, though the most likely diagnosis was carcinoma. It was believed to involve the entire stomach. Gastroscopy was done and the gastroscopist thought the esophagus might be involved. Because of the likelihood of the tumor being lymphosarcoma x-ray radiation was given prior to operation but without effect. A subtotal gastric resection, aseptic in type, was done without event. Enteroanastomosis was also made. Patient died of pneumonia six days after operation. There was also a pneumococcal peritonitis regarded by the pathologist as being hematogenous in nature. The suture lines were all intact. The operation lasted three hours. The pneumonia was treated by anti-pneumococcus serum.

Comment

I have little to say in justification for this increased mortality rate other than to indicate that resection has been extended to an increasingly larger number than heretofore of the patients explored for carcinoma of the stomach. The incidence of resection in the group here reported, I am embarrassed to say, exceeds the highest figure found in surgical literature by Livingston and Pack—that of Finsterer of Vienna, who resected 329 out of 518 cases (63.5 per cent). Finsterer's mortality for the group was 19.4 per cent. According to Livingston and Pack, Lahey's series of fifty resected cases among 109 operated upon constitutes the second highest reported resection rate (45.8 per cent). The mortality in Lahey's group was 34 per cent. Surgeons still have the enviable record to emulate of a 5 per cent mortality in 200 consecutive gastric resections for gastric cancer reported by Balfour. That gastric resection is a highly specialized type of surgery is well attested in Balfour's unusual accomplishment.

The oldest patient who survived resection in this group was seventy-eight years. I have previously had a patient of seventy-nine years survive resection for gastric carcinoma, and in a patient of eighty-one operated upon for gastric carcinoma the lesion turned out to be a benign ulcer! The patient survived.

There were nine patients over seventy in the present group and eighteen were more than sixty-five years of age. The youngest was forty-five years. There were three diabetics in the group. Two survived operation. One (Case 7 above) died of hypoglycemia from the administration of too much insulin. One patient of seventy-one (Mr. R. J., U.H. No. 685614), not counted in the operative mortality, after being ambulant for more than a week following operation, died of a small perforation in the gall bladder twenty-six days after operation. There have been no deaths in the last eleven resections done for gastric cancer.

One of the deaths listed above (Case 4) was a surgical blunder. However, I have since learned how one may now and then deal with the occasional case of this sort in which stomach, pancreas and carcinoma are fused into a single ill defined mass. By dividing the stomach proximal to the lesion and leaving the perforated portion of the carcinomatous posterior wall of the stomach upon the pancreas, the plane of cleavage between antrum, pylorus, duodenum and pancreas can be defined from above downward, usually without too great difficulty. With employment of traction upon cats-

paw retractors from alternate directions, the residual carcinoma can be shaved off the pancreas usually without great hazard. The defect in the pancreas is then to be repaired with placement of interrupted Halsted mattress sutures of fine silk. If the defect is too large to close satisfactorily the omentum can be sewn over it.

One of the most instructive deaths is that of Case 3, above, in which gangrene of the afferent loop of the jejunum occurred. A few similar instances reported in the surgical literature have come to the writer's notice. It is a wholly avoidable accident. Routine performance of entero-anastomosis between the afferent and efferent loops after gastric resection for carcinoma obviates its occurrence.

In another instance, that of Case 1 above, evisceration was the main surgical complication leading to a fatal outcome. Use of the left subcostal incision and closure of the wound with interrupted sutures of silk has done away essentially with this complication. No eviscerations have occurred now for a period of more than two years. At one time in this clinic, when closures were made regularly with running sutures of chromic catgut, evisceration was observed, following gastric resection for carcinoma, more commonly than following any other type of operation. In this instance and in one other, amongst the fatal cases, a small abscess was found on postmortem examination, at the site of duodenal closure.

One of the most difficult hurdles for all surgeons, in gastric resection, is acquisition of a safe method of inverting the duodenal stump. Use of a crushing clamp accompanied by over-sewing with several layers of running sutures of catgut will undoubtedly result in duodenal fistula in a number of instances, despite satisfactory inversion. For some time now, the writer has used the Petz sewing apparatus, after separating the medial wall of the duodenum adequately from the pancreas. A single row of interrupted mattress sutures of fine silk of the Halsted pattern is employed to secure duodenal inversion. Three additional sutures are placed anchoring an omental tab over the inverted duodenum.

More and more I have come to learn that pneumonia is, in part, a direct surgical complication. Commonly after a long operative procedure, the patient leaves the operating room with moist trachea and bronchi. The use of suction applied to an indwelling gastric tube prior to, during and after operation does away with the feature of aspiration. It is important, however, during and after operation, to employ the Trendelenburg position to avoid aspiration. Further, bronchoscopic aspiration of the trachea and bronchi by the anesthetist (a new function for him) directly after the completion of the operation, I have a feeling, will help materially in reducing the incidence of atelectasis and postoperative pneumonia. In the pneumonias which occur nevertheless, employment of sulphapyradine will reduce materially the incidence of mortality through this agency. In one of the cases, Case 5 above, uremia, consequent upon urinary retention, necessitating use of an indwelling catheter, was the immediate cause of death. For a period of some time now I have given patients needing indwelling urethral catheters after operations, because of urinary retention,

sulphanilamide subcutaneously. Its administration serves quite effectually, apparently, to obviate pyelonephritis, oliguria and uremia, and constitutes a useful means of helping to avoid complications which spell added mortality. When the carcinoma is perforated onto the pancreas, sulphanilamide is given also subcutaneously for a few days postoperatively.

Cures

It is not so long ago, that carcinoma of the stomach was despaired of as being a hopelessly incurable disease. Perusal of Livingston and Pack's monograph on gastric cancer will suffice to convince any doubting Thomas that such is no longer the case. It is, of course, important that all stubborn opposition to operation in gastric cancer be broken down. It would appear from the review of Livingston and Pack that in the group of patients surviving resection, the ultimate cures compare favorably with other intraperitoneal malignancies such as those of the rectum and colon.

Dr. George Bergh found somewhat more than a year ago in studying the fifty-seven patients who had then survived resection for carcinoma of the stomach and were well without evidence of return of the disease: one patient well ten years after resection; one eight years; one seven and a half years; one seven years; one five and a half years; another five years; and a fairly large number under five years.

Livingston and Pack, from an intensive study of the literature of reported cases, have compounded a formula to determine the likely survival periods in the resection cases. They found that, of patients surviving resection for gastric cancer, 20 per cent will live ten years, 25 per cent will survive for five years, and 33 per cent for three years. Of those patients not accepting resections the average survival after the diagnosis is made is four months. Expressed in a formula, the short term survivors in a given series (that is, those not surviving ten years) are lumped together as twenty months. The calculation for the thirty-nine patients reported here would be as follows:

Expected survival had none been operated on— 39×4 months = 156 months

Shortening of life incident to operation—8 deaths $\times 4$ months = 32 months

LIVINGSTON AND PACK'S CALCULATED SURVIVAL

20% of 31 cases = 6.2 should survive 10 years

$6 \times 120 = 720$ months

The remainder,

$31 - 6 = 25$ should survive on the average 20 months

$25 \times 20 = 500$

Total $720 + 500 = 1220$ months

Shortening of life by operation,
8 cases — 32
1188 months

The expected survival of the group without operation — 156

Estimated saving of life by operation in this series of patients
= 1032 months — 86 years.

It is obvious, therefore, that a radical operation does afford the patient with a resectable lesion a fairly bright prospect when contrasted with his expectations without operation. It is extremely unfortunate, however, that so large a percentage of a group of gastric carcinomas are inoperable when first seen.

Diagnostic Considerations

At the University of Minnesota carcinoma of the stomach is not being diagnosed any earlier during the course of the disease than it was four years ago. In the majority of instances the delay is owing largely to the time interval which elapses before symptoms are sufficiently characteristic to direct the attention of the patient or his physician to the stomach. This is true also when the patient happens to be a physician, a surgeon or even a gastric surgeon. The x-ray is still the most important agent in the detection of the presence of carcinoma of the stomach. My associate, Dr. George S. Bergh, found in studying a series of patients operated upon for carcinoma of the stomach at this hospital that the accuracy of roentgen diagnosis on the positive side was 86.5 per cent. With reference to basal indications for operation, roentgen opinion had an accuracy of 94.2 per cent.

At the time of the previous report four years ago, a patient, Mrs. M. E., U. H. No. 645079, had just been observed, in whom the diagnosis was established on gastroscopic examination, when x-ray examination was entirely negative. In the intervening years, in only one additional patient has the diagnosis been made by gastroscopic examination when x-ray examination failed to disclose the nature of the lesion. This patient, Mr. S. D., U. H. No. 686051, at operation, proved to have a large annular polypoid carcinoma on the anterior gastric wall high up near the cardia. The crater of the carcinoma measured 9 centimeters across. Subtotal gastric resection was done without event. Dr. Cecil Watson, under whose observation the patient came, suspected the presence of gastric carcinoma because of blood in the stool, anemia and weight loss. Gastroscopic examination is, therefore, a useful expedient as a diagnostic procedure. Fluoroscopic and roentgen observations in the hands of an expert will, however, reveal a higher incidence of positive diagnosis. The weakness of gastroscopy lies in failure to secure material for histologic diagnosis. A fairly large number of patients with carcinoma of the stomach have free hydrochloric acid after histamine, on gastric analysis.

Pathological Considerations

It may be said that polypi are amongst the more frequent known precursors of carcinoma of the stomach. So frequently do gastric polypi become malignant that their presence constitutes a satisfactory indication for operation. Gastric polypi are associated with achlorhydria to histamine in about 90 per cent of cases. Konjetzny has stressed gastritis as an antecedent predisposing cause of gastric malignancy. Konjetzny insists that carcinoma of the stomach never develops on a normal mucous membrane. The interstitial variety

of gastritis characterized by lymphocytic invasion of the stroma of the submucosa is generally recognized by pathologists. The variation in cell structure of the gastric glands is not so well understood, however. The atrophic gastric mucosa with polypoid elevations in which achlorhydria is concomitantly present, is probably a frequent precursor of gastric carcinoma. Since patients with an atrophic gastric mucosa and suffering from pernicious anemia are surviving for longer intervals, gastric carcinoma in this group is being more commonly observed. There are two such patients in this group: one in the resection series; the other in the group for which gastro-enterostomy was done.

Gastric ulcer is probably an infrequent precursor of carcinoma of the stomach. Dr. William MacCarty of Rochester reports the frequent presence of secondary cytoplasmia in gastric ulcers—a finding which he has not observed in duodenal ulcers. The best available factual data,^{3,4} however, suggest that carcinoma of the stomach does not develop upon a preexisting ulcer in more than 3-5 per cent of instances. The possibility of confusing gastric ulcer and carcinoma is a much more pressing question. There are instances in which a satisfactory differential cannot be made by x-ray examination, observation in bed under well supervised medical management or by the surgeon at operation. In many such instances the pathologist finds it necessary to study many blocks after paraffin fixation, in order to determine satisfactorily whether the ulcer is benign or malignant.

Prinz of Kojetzny's clinic in Hamburg has described recently prepyloric defects in which the musculature is thickened in which roentgenologist, surgeon and even the pathologist have difficulty determining with definiteness whether the lesion is benign or malignant. I have seen instances of this sort. Some are undoubtedly instances of hypertrophy of the circular muscle of the pylorus of the adult. In others, however, the defect is definitely prepyloric. On section the muscle appears thickened. There may also be polypoid thickening of the mucosa overlying the muscle at this level. Prinz believes that this condition represents a precursor stage of carcinoma of the stomach. I have seen instances of this sort.*

Surgical Considerations

Preoperative Preparation.—Patients in good physical condition without obstruction and exhibiting no evidence of anemia require no special preoperative preparation. Patients with obstruction need a preoperative period of observation in which the stomach is aspirated frequently. Mild retentions respond favorably, usually, to morning and evening aspirations and ingestion of only clear liquids. We have tried frequently in instances of high grade obstructions, due to carcinoma,

*Two recent cases observed since the time of this report have exhibited findings described by Prinz. Mr. O. B., U. H. No. 671852, age 73, presented such polypoid thickening of prepyloric and antral mucosa. Mr. T. L., U. H. No. 686930, age 65, exhibited definite thickening of the prepyloric circular muscle and of the mucosa. Both conditions after histologic study were found to be benign. Gastric resection was survived without special incident in both cases.

to get a tube through the pylorus. Almost uniformly, these attempts have come to naught despite many improvisations. Such patients usually need an indwelling gastric tube to which suction is applied to forestall the occurrence of vomiting.

Far more important, however, such patients also usually have anemia, low plasma proteins and not infrequently edema. Careful pre- and postoperative administration of fluid in suitable amounts, with special reference to chloride and caloric needs and adequate hydration, are very important considerations. Such patients may be given *too little* chloride, as well as *too much*. As suggested by Paine and Armstrong, careful daily computation of the sodium chloride in the urine and in the gastric aspirations affords, in the main, a very satisfactory check.

A number of patients with low plasma protein and anemia must have a large number of transfusions of blood or serum prior to operation. If the physical status and the local lesion will permit, I prefer to operate upon such patients in one stage rather than two, knowing that more patients will be accorded the opportunity of having the complete operation.

The Operation.—The patient arrives in the operating room with an indwelling gastric tube in place and the stomach empty. Suction is in force during the operative procedure. My choice of anesthetic is intratracheal cyclopropane. A left subcostal incision affords a more satisfactory exposure of the upper reaches of the stomach than any other. For some period of time now, I have been employing the closed or aseptic technic in all gastric resections. It is a more painstaking procedure, in that all the sutures are interrupted. I have the impression, however, that he who comes to adopt the aseptic method of gastric resection is not likely to give it up, because of the somewhat longer time necessary to perform it. The element of *hurry*, so much talked of in abdominal surgery two and three decades ago, has largely disappeared. With good planning and skilfully administered anesthesia the primary question now is, not *how quickly* but *how well* the operation is done.

The technic of the performance of aseptic gastric resection has been described in detail elsewhere¹⁵ and will not be repeated here. An entero-anastomosis between the afferent and efferent limbs of the jejunum, employed in the gastro-jejunal anastomosis, is always made to avoid the complication referred to above (Case 3). It does away largely also with the item of postoperative gastric retention.

All sutures are of silk, those employed in the anastomosis, as well as in closure of the abdominal wall. A small mastisol dressing, slightly wider than the incision, suffices as a satisfactory covering of the wound. No adhesive tape or abdominal binders are employed. Closure of the peritoneum and fascia with interrupted mattress suture of silk placed after the Halsted mattress pattern has done away with the complication of evisceration.

When the peritoneum is closed, the patient is placed in a fairly steep Trendelenburg position to encourage

gravitation of any bronchial mucus into the trachea. On completion of the operation, bronchoscopic aspiration of the trachea and bronchi is made by the anesthetist, or if the patient appears dry, aspiration of the trachea with a tube inserted through the indwelling intratracheal tube suffices.

I have come to prefer palliative gastric resection to gastro-enterostomy, where enough normal stomach tissue remains to make a suitable anastomosis. In frankly inoperable patients, a Pezzer catheter placed in the jejunum for purposes of feeding at the time of exploration helps the patient over the trying last few months of his illness.

Postoperative Treatment.—The patient is placed in his bed and maintained in a fairly steep Trendelenburg position till awake. The Trendelenburg position is maintained throughout the first half of the convalescent period at a lesser angle. Fowler's position is not employed. The patient is encouraged to move about in bed as much as he can after waking. Nurses and house officers enjoin upon him the importance and necessity for him "to move his arms and legs a thousand times a day." The nurse holds the patient's chest to avoid strain on, or pain in, the incision, and encourages him to take deep breaths and to give three or four coughs, a dozen or more times a day. Suction is applied to the indwelling gastric tube on return to the ward and is maintained, uninterrupted, for forty-eight to seventy-two hours, after which time it is clamped occasionally and then removed. Para-oral fluids are given largely subcutaneously to the older age group of patients, 5 per cent glucose in distilled water and 5 per cent glucose in saline solution being given, the amounts of each depending on the chloride and water requirements of the patient. The patient may drink water by mouth in small amounts as soon as he is awake.

Feeble patients past the mid-seventies, as well as debilitated patients at younger age levels are given oxygen directly after operation. If there is any suggestion of mucus in the throat which the patient cannot raise, repeated pharyngeal and intratracheal suction is practiced.

Summary

Carcinoma of the stomach is the most common of all malignancies and is responsible for more deaths than any other malignancy. Of patients presenting themselves in a satisfactory physical status and with a lesion still local in the stomach, resection may be accomplished with a reasonable risk and a reasonable chance of cure. Amongst the resectable group of gastric malignancies, cures compare favorably with other visceral malignancies, such as those of the colon or rectum. Unfortunately, a large number of patients still come to hospital with gastric cancer when the condition is beyond remedy. To make this group smaller, needs the concerted vigilant effort of patients, physicians and all medical and surgical specialists.

DR. S. R. MAXEINER: It has been a pleasure to hear Dr. Wangensteen's discussion of gastric surgery at the University. I have been particularly interested in the work which he is doing with the aseptic anastomoses. Many of us have been using aseptic anastomoses for a number of years, particularly as applied to the colon. We have personally not applied it in resections of the stomach as we have preferred to do these resections without clamps, ligating all bleeding points as they are encountered. However, I am sure that I shall be using aseptic anastomoses more generously in the future.

Many years ago Cushing did a very extensive piece of work on the bacterial flora of the stomach and intestinal tract, and showed definitely that the bacterial flora of the stomach and intestine could be altered and the number of pyogenic organisms increased or decreased by the character of the food ingested. I believe that this is particularly applicable in cases where there is achlorhydria. Obstructive lesions with retention also favor bacterial increase. As a result, we have routinely taken at least three days to prepare our gastric cases by the use of sterilized food, the administration of hydrochloric acid and the repeated washing of the stomach with weak hydrochloric solutions. Those patients who have obstructive lesions at the pylorus are more thoroughly prepared and no residue is allowed to remain in the stomach overnight. In this manner we have avoided the use of clamps, cut down the number of postoperative hemorrhages and we believe we have also decreased the amount of postoperative peritonitis.

In a review of the literature which I did for this Society in 1935 on carcinoma of the stomach, it was interesting to note the reports of various clinics as to the increased operability of the surgically treated carcinomas of the stomach. It seems to me one must bear in mind that there are other things than cure alone to be anticipated in treatment of carcinoma of the stomach. Finsterer states, "Without resection every patient will die, and die in pain and misery. Therefore, I must resect whenever possible." The purpose of many of these resections, according to Finsterer, are therefore palliative. The observation of many surgeons of large

experience revealed the fact that even palliative procedures in which the primary lesion is removed, result in prolonged recession of the metastases so that the patient often lives many years without demonstrable recurrence.

We recently performed an exclusion operation on a patient of 81 years who was suffering from severe pain from far advanced carcinoma and continued hemorrhage. He was being transfused every ten days to maintain his hemoglobin. In the exclusion operation as advocated by Balfour and which Dr. Cranmer has just stated is now being used by Lahey, the stomach was divided proximal to the growth, the distal end of the cut off stomach was inverted and the proximal cut off end was anastomosed to the jejunum. This patient has had a great deal of relief from pain. It is now nine months and although he still loses some blood in the stool he has had fewer transfusions and is able to take all types of food without retention and without pain.

I think our profession has been grossly remiss in its attitude towards carcinoma by accepting such a dubious, helpless attitude. We reported 18 resections which we realize is a comparatively small number but of these, one died at the end of five years from tuberculosis and autopsy showed that there was no recurrence at the end of this period of time. I assisted Dr. Lee seven years ago in removing a stomach cancer in an elderly woman who is still perfectly well and able to do her own work. Another patient whom I resected seven and one-half years ago remains perfectly well without symptoms of recurrence. In other words, approximately 17 per cent of the eighteen cases reported have survived five to seven and one-half years.

SURGERY OF CARCINOMA OF THE COLON

ORWOOD J. CAMPBELL, M.D.
Minneapolis

Because it is frequently encountered, yields a relatively high percentage of cures, yet carries a high operative mortality, cancer of the large bowel continues to command the special interest of the abdominal surgeon. In no field of surgery is the operator better rewarded for the careful evaluation of all the factors bearing on his patient's condition and the judicious selection of the proper surgical procedures.

The utter impossibility of standardizing the treatment of carcinoma of the colon except as to broad principles is at once apparent when one considers the numerous procedures available, the variable factors affecting the operative risk and end result and the conflicting opinions and results recorded by able and experienced men.

As my contribution to this seminar I propose to examine some of the ideas and results of other men, to report a very limited experience of my own and generally to assist in the clarification of surgical principles which will permit the more complete individualization of treatment under any group of circumstances.

History

The evaluation of present day operative procedures with their lower mortality rate is a striking illustration of the progress of which surgery is capable.

The first successful resection was reported by Kohler in 1881. Before 1889 seventeen cases of resection had

been reported with ten deaths or a mortality of approximately 60 per cent. In the next ten years fifty-seven cases were published with 37 per cent mortality. The prevailing method was resection with end to end suture.

The two-stage operation was suggested in 1890 by Heinecke who did not himself report any cases. Oscar Block of Stockholm recorded the first case of extra-peritoneal resection in 1892. Allingham, Edmunds, Hahn, Hockenegg and Rotter reported cases in the next two years. In 1895 Caird reported a successful case and in the same year Paul of Liverpool published his classical article in the British Medical Journal recording his first case treated in 1892.

Mikulicz, who did his first two-stage operation in 1898, described his exteriorization procedure in 1903, reporting sixteen cases with an operative mortality of 12.5 per cent, a rate which is creditable even today.

Only a few technical procedures have been added since. The more important are the development of aseptic technics for resection; Rankin's modification of the Paul-Mikulicz exteriorization procedure which he calls obstructive resection; and finally Devine's colostomy for the complete "defunctioning" of the distal segment containing the tumor.

Management of Obstruction

Aside from inherent factors such as the highly infectious nature of the bowel content and its uncertain and limited blood supply, those variables which operate against the success of surgery are not so much the cancer itself as the complications of the cancer. Extension of the tumor into neighboring organs, metastases, perforation with local abscess or peritonitis and most important of all, obstruction, are the obstacles to successful surgery.

Carcinoma is overwhelmingly the most common cause of obstruction of the colon. Rankin states that between 75 and 80 per cent of patients with colonic cancer have obstruction at the time they first consult a surgeon. Obstruction in the left half of the colon is eight times as common as in the right half. Burgess found evidence of acute obstructions in 35.6 per cent of 458 cases of carcinoma of the colon. Of Graham's thirty-three cases, 50 per cent were admitted with acute obstruction.

That acute obstruction of the colon is a serious condition is evidenced by a mortality rate of from 30 to 50 per cent in procedures designed only to relieve the obstruction. The work of Sperling, who demonstrated the competency of the ileocecal valve, establishes such an obstruction as of the closed loop type. A dog's colon subjected to an intraluminal pressure of from 30 to 50 cm. water will develop gangrene and necrosis of the bowel wall. Intraluminal pressures within this range were found in cases of colonic obstructions. Of twenty-six cases of acute obstruction at the Minnesota General Hospital there were nine deaths, eight of which were due to peritonitis as a result of perforation of the cecum or bowel wall proximal to the tumor.

Even incomplete obstructions are dangerous to the

patient. Proximal to the obstruction the bowel wall is distended, inflamed and edematous. In this state the permeability of the bowel wall to pathogenic organisms is greatly increased predisposing to pericolic inflammation and peritonitis, especially if the bowel is handled. In addition, stasis of contents results in a greatly increased bacterial content and increased toxicity.

As early as 1900 Körte collected fifty-eight cases of intestinal obstruction caused by colonic carcinoma with an operative mortality of 60 per cent. Exteriorization was done in eleven with 63 per cent mortality. Finster's operative mortality was 29 per cent in thirty-four cases admitted with acute obstruction and 14.7 per cent in sixty-one cases without obstruction.

There has been such unanimity of experience in dealing with obstructions that the surgical principle is firmly fixed that no direct attack on the neoplasm can be undertaken until the obstruction is relieved either by surgical or non-surgical means. In all cases of incomplete obstruction a so-called medical decompression should be attempted. This consists of a low residue diet and the oral administration of mineral oil or magnesium sulphate to liquefy the contents of the bowel. In addition oil and water or saline enemas are administered under low pressure. Successful decompression is recognized by the relief of obstructive symptoms, diminution of retained gas in the colon by x-ray and decrease in the number and volume of the liquid stools.

In acute colonic obstructions of complete or near complete degree, surgical decompression is indicated. The four procedures which may be utilized are colostomy, cecostomy, appendicostomy and ileostomy. Because of the competency of the ileocolic valve, ileostomy is of little value in decompressing an obstructed colon unless a tube be passed through the valve into the cecum. Appendicostomy has a very limited value because of the small size of the tube which can be passed through the appendiceal stoma. Neither appendicostomy or cecostomy diverts the fecal stream and is therefore less efficient than a colostomy of the permanent type with raised spur (permanent type).

Proponents of cecostomy, such as Roscoe Graham, Wilkie, Lockart-Mummery and many others, admit its limitations as a means of decompressing the colon but like it because of its simplicity. In the experience of others, Cheever, Wangenstein, Rankin, Sperling, cecostomy is either dangerous or inadequate.

Two indications for cecostomy seem logical:

1. Relief of obstructions in the ascending colon or hepatic flexure.
2. As a safety valve done coincidentally with a suture anastomosis of the bowel.

A transverse colostomy as an efficient means of decompressing the colon, is most favored. Wangenstein recommends a transverse incision through the right or left rectus. The transverse colon is brought out and held by a glass tube which is passed through the margin of the mesentery. The wound is closed around the bowel. Sutures may be inserted in the

fatty appendages but must not be inserted in the bowel wall. Gas and fluid may be aspirated or removed by a catheter held snugly in the bowel by a purse string suture. After forty-eight hours the wound has sufficiently sealed so that the bowel wall can be opened by cautery.

An impressive amount of statistical evidence is available to show that when extirpation of the malignant growth is preceded by decompression procedures the operative mortality is reduced by one-half or even two-thirds. Cheever, Finsterer, Gordon-Watson, Roscoe Graham, Von Haberer, Allen and Paus are only a few who have so reported.

Devine with his so-called "defunctioning" type of colostomy carries to the extreme the principle of relieving obstruction in the large bowel and in so doing reduces the bacterial count to a point where relatively extensive malignancies and inflammatory lesions may be removed by open suture anastomosis and with low mortality rates.

I have had one interesting experience which has led me to believe that the full possibilities of non-surgical decompression have not been realized. An elderly man was brought to Minneapolis with complete obstruction due to a carcinoma of the sigmoid. The abdomen was grossly distended. There was no vomiting. A flat plate of the abdomen revealed enormous distention of the colon. The patient was given three to four ounces of mineral oil daily by mouth and placed on a non-residue diet with the additional support of glucose solution administered intravenously. On the seventh day, because we despaired of opening his obstruction medically, he was operated upon. The transverse colon could not be delivered because of the distention but was brought up to the abdominal wall and vaseline gauze packed into the wound ready for later opening. Later, on the day of operation he began to pass large quantities of liquid stool per rectum. Colostomy was never completed. After three weeks his tumor was resected and end to end anastomosis done over a Rankin clamp. The condition of the colon at the time of operation gave no indication that obstruction had ever been present.

This, together with other less striking experiences, has led me to believe that with sufficient time and the use of large quantities of mineral oil even high grade obstructions may be relieved by non-surgical means, thereby eliminating one stage in the operative removal of cancer of the colon.

Preparation of the Patient

While the relief of obstruction is the most important of all preoperative considerations, other measures are of great importance. Dehydration and depletion of liver glycogen should be combated by intravenous glucose solution. Anemia, so common in right sided malignancies, must be overcome by transfusions and hemopoietic stimulants.

As a result of infections associated with ulcerated processes in malignant lesions it has been shown that a marked vitamin C deficiency always occurs. Lanman, Thomas and Ingalls, Taffel and Harvey and others

have shown that vitamin C deficiency interferes with wound healing. Two hundred mg. of cevitamic acid daily is sufficient to restore the deficiency. Vitamin B has a stimulating effect on appetite and on the tonicity of the large bowel. Its use is indicated preoperatively.

Efforts to increase the resistance of the peritoneal cavity to infection by the intraperitoneal injection of vaccines and various substances began in 1887 when Pawlowsky used croton oil to produce peritonitis in experimental animals. Subsequent work established the protective value of exudate in peritonitis but has not established the advisability of routine vaccination. The three most commonly used immunizing agents are:

1. Steinberg's coli-bactragen.
2. Bagen's strap and coli vaccine.
3. Amoniotic fluid.

Rankin, Bagen and Dixon popularized the use of intraperitoneal vaccines. Dixon still advocates their use.

Coller and his associates believe that the routine use of vaccines is not needed or desirable but believe when spillage of infective material accidentally occurs at operation the use of some substance which produces a rapid leukocytic response on the part of the peritoneum is of value. Steinberg's coli-bactragen has been most satisfactorily and extensively used by them. With this view Oschner and Allen are in complete accord.

The omnipresent sulphanilimide bids for a place in the preoperative preparation. Gailoch and Seley made cultures from the bowel wall in six carcinomas of the colon. In four, streptococcus hemolyticus in conjunction with bacillus coli were recovered. In twenty-one cases in which the blood sulphanilimide level was maintained at 5 to 6 mg. per cent for three days prior to operation streptococci, were not obtained and no peritonitis occurred.

Choice of Operation

Considerable disagreement is evidenced among surgeons of equivalent experience as to what constitutes the safest and most effective procedures. That technical considerations are important is suggested by the very considerable difference in results shown by different men with the same methods and under presumably similar conditions.

For example, Lahey advocates an exteriorizing operation in surgery of the right half of the colon. In his hands the procedure is safe and effective. Others who have tried it condemn it because of a high mortality rate. Cheever gets better results with open suture anastomosis. Rankin and others condemn it.

In the right half of the colon where feces are fluid, obstruction rare, blood supply scanty and lymphatics plentiful, the surgeon must choose between Lahey's exteriorizing operation, hemi-resection of the colon with ileocolostomy either as a preliminary or as coincidental procedure and resection with suture anastomosis either by aseptic or open technics.

In the transverse colon the surgeon must choose between an exteriorization procedure of which Rankin's

obstructive resection is most favored, or resection with end to end or side to side anastomosis. He must also decide whether a preliminary or coincidental cecostomy or colostomy is to be done.

In the sigmoid and recto-sigmoid the choice rests between obstructive resection and resection with end to end anastomosis. He must decide whether a preliminary colostomy is needed and whether of the ordinary spur type or of the Devine "defunctioning" type. When the lesion is low, the question is raised whether the rectum can be saved and if so whether restoration of continuity can be accomplished at the same or later time.

If one seeks the answer to these questions in the experience of others, considerable confusion arises. While there is fairly uniform agreement on the broad principles involved there is much difference of opinion in their application.

A surgeon may produce extremely favorable statistics as an argument for his particular procedure if he considers as inoperable all tumors showing adhesions to surrounding the organs or showing lymphnode enlargements. Unless he realizes that both adhesions and lymphadenopathies may be inflammatory and not malignant he is denying the right of cure or palliation to a considerable number of patients. In a series of twenty-six articles an operability of over 50 per cent is reported in two-thirds and slightly under 50 per cent in the remaining third.

In a series of 2,991 cases collected by Ochsner the mortality was 21.7 per cent. The lowest was 3.1 per cent in a series of thirty-two cases and the highest was 63 per cent of twenty-seven cases. Of 3,911 resections 30.7 per cent were alive and well five years. The highest incidence of five-year cures was obtained by Oughterson and Shelton: 52.6 per cent of a series of 131 cases.

There are few statistics to indicate the advantage of an aseptic anastomosis over open suture but those available show a small advantage in favor of aseptic methods. McFee reports a 16.1 per cent operative mortality in fifty-six cases where aseptic anastomosis was done and 18.8 per cent of thirty-two cases in which open anastomosis was done. Allen and Welch report 11 per cent operative mortality in fifty-two cases using the Parker-Kerr aseptic technic and 23 per cent of thirty-eight in open anastomosis. The same authors show 22 per cent mortality in eighteen cases in which clamps were used to effect aseptic suture. Stone and McLanahan show an operative mortality rate of 11.2 per cent for seventy-one cases in which aseptic anastomosis was done while in nineteen cases of open anastomosis there was a 26.3 per cent mortality.

Until recently it was the consensus that right sided lesions could be safely resected in one stage. Recently Allen, Rankin, Abell, Cheever, Paus, Guy Turner, Dixon have produced figures indicating that the operative mortality is distinctly less when preliminary ileocolostomy is done. Lahey's exteriorization operation for right sided lesions, while successful in his hands, has not received general acceptance. At the University of Minnesota it has been abandoned because

of a prohibitive mortality. It has the disadvantage that the greater procedure comes first and in cases of obstruction or inflammation, it does not provide for a preliminary diversion of the fecal stream.

The exponents of the single stage suture anastomosis are comparatively few. Wilkie and Lockhart Mummery favor it. Cheever and C. W. Mayo recommend resection and end to end suture in the transverse colon. The former reports an 18 per cent mortality in eleven operations and the latter 11 per cent in thirty-six cases. In ninety-five cases where obstructive resection was done on the transverse colon, C. W. Mayo had a 20 per cent mortality rate. He concluded that end to end aseptic suture in the transverse colon is a safer procedure than exteriorization. The average hospital stay in the former was twenty days and in the latter fifty-nine days. Stone and McLanahan report seventy-one cases of aseptic end to end anastomosis with 11.2 per cent mortality.

After a preliminary decompression there is a greater readiness to resect and to do a primary anastomosis. Allen and Welch record their lowest mortality rate when end to end suture is done. Devine, after he has "defunctioned" the bowel for a month, removes the cancer and either does an immediate end to end suture or more often implants the end of the bowel in the abdominal wall, waits a longer time before establishing continuity of the bowel.

In low carcinomas of the sigmoid or high recto-sigmoid malignancies, where exteriorization is difficult or impossible and where the resection of the tumor destroys the superior hemorrhoidal artery, Devine's method of closing the rectum and suturing the lower end of the sigmoid in the wound makes it possible to save the anal sphincter. Dixon utilizes a procedure of a similar nature using one less stage, in that the resection and anastomosis are accomplished at the same time. In his experience the middle hemorrhoidal arteries have always proven adequate to maintain the viability of the rectum.

The feeling is definitely against end to end suture in the descending colon and sigmoid. Even in the transverse and proximal colon the few advocates recommend either a preliminary or coincidental cecostomy or colostomy. Yet in thirty successful cases of suture anastomosis in the transverse and left colon Cheever reports eight who had no preliminary or simultaneous colostomy. None developed leaks.

He apologizes for his temerity with the statement, "This again illustrates how misleading statistics may be, for certainly no surgeon of experience would advise primary resection with suture anastomosis without making a proximal safety valve."

Although the series is small, I wish to report my limited experience with twelve carcinomas of the colon treated by one stage resection and end to end anastomosis without preliminary or simultaneous colostomy or cecostomy. Nine of the eleven cases were in the sigmoid and descending colon, one was in the splenic flexure, one in the transverse and one in the ascending colon. There was one operative death. This man developed pneumonia late in his convalescence.

At autopsy the suture line was solid and the peritoneum clean.

These cases were all ideal for any type of operation. In only one, as recently described, was there high grade obstruction and in this case non-operative means removed every residual of obstruction within three weeks. All received mineral oil by mouth, were kept on a non-residue diet for three to five days and given daily enemas.

The anastomosis was done over a Rankin clamp. In earlier cases two rows of continuous cat gut suture were used. Later the first row only was of cat gut, the outer row of silk. In every case fatty tags and omentum were utilized to cover the suture line.

Post-operatively the patient was maintained on 2,000 c.c. 10 per cent glucose solution daily given intravenously. Nasal suction was started immediately and mineral oil on the second or third day. A rectal tube was inserted for alternate hours after the first day. Most patients passed liquid stool about the fourth or fifth day. Convalescence was remarkably uneventful. In no case was there more than slight distention. There was one wound infection, no fecal fistula.

The cases are too recent to determine the outcome. One woman had a Krukenberg tumor at the time of resection and subsequently died of cancer. One man developed a recurrence near the site of resection and was successfully reoperated with the establishment of a permanent colostomy. It is probable that he will develop other metastases.

The technic is exacting and time consuming. Meticulous care is needed to preserve the blood supply. The clamps should be applied obliquely to protect the viability of the suture line at its anti-mesenteric border. It is advisable to test the effect of obstructing every major blood vessel before it is permanently crushed. On one occasion an intended local resection of malignancy of the ascending colon had to be converted to a resection of the right half of the colon because what appeared to be a minor artery, when ligated, cut off the supply to the entire cecum.

None of these cases was operated with the predetermined object of doing this type of anastomosis. Had there been any evidence of obstruction or inflammation, obstructive resection would have been done. They were so operated because they were ideal cases and because the premise was entertained that under ideal conditions and using an aseptic technic for anastomosis there should be no additional hazard to the one stage operation. By withholding food and by giving relatively large quantities of mineral oil the contents of the left half of the colon may be kept fluid enough to pass through the stoma of the anastomosis. The rectal tube sufficed for the relief of gas, although had gross distention occurred, cecostomy could have been done.

The graded type of operation has proven its safety and effectiveness. No principle in colon surgery has been more completely established and accepted. Nevertheless, there are cases in which multiple stage procedures seem unnecessary and advantage may be taken of the savings in time, expense and discomfort which the single stage operation affords.

Twelve cases is too small a series from which to draw any conclusions. Many men of far wider experience have condemned the one stage procedure on the left colon. For the present I shall persist in my belief that under ideal conditions the single stage resection with aseptic anastomosis is a reasonable, and relatively safe procedure and that by using large quantities of mineral oil, low residue diets and plenty of time patients with relatively high grade obstructions may be completely decompressed and saved the necessity of a preliminary colostomy.

Discussion

DR. E. A. REGNIER: I think Dr. Campbell has had a unique experience in his success with eleven colon resections with primary anastomoses. I will frankly admit that my experience is much more limited. Surgery of the colon is so often complicated by either obstruction, inflammation or perforation that I have chosen the more conservative operation, namely, the modified Mikulicz operation. This operation lends itself to more lesions of the large bowel than any other one operation that I know of and with a greater degree of safety. I was impressed early in medicine by the danger of doing an anastomosis of the colon without a previous decompression operation. By thoroughly mobilizing the colon and by staggering the proximal or distal loop, extensive resections may be done in any portion of the colon, permitting exteriorization of the contaminated bowel. Obviously, as Dr. Campbell has shown, the ideal case may be safely resected and anastomosed in one stage. I believe no discussion of surgery of the colon should

be closed without calling attention to the lack of early diagnosis of these lesions, thereby raising the percentage of curable cases.

Lahey has shown that 75 per cent of all carcinomas of the colon occur between the splenic flexure and the anus. He has also shown that 65 per cent of the polyps and pedunculated adenomas occur in this same position of the bowel, hence the close correlation between these so-called innocent lesions in the occurrence of carcinoma. The early findings and removal of these lesions would probably prevent many carcinomas or would certainly lead to early diagnosis. All authors agree that 95 per cent of people with lesions of the colon have an antecedent of marked alteration in bowel habit. I believe that earlier diagnoses of malignant lesions of the colon and bringing these people to operation at a time when the lesions are purely local would raise the percentage of operability and would probably select lesions which could be removed by less complicated procedures.

ADVERSE SOCIAL FACTORS

Adverse social factors have significance in medical care chiefly because of their power to disable. Deprivations, strains and dissatisfactions have physiological effects such as depletion of bodily substance, fatigue and emotional tension which are of special importance in aggravating disability already started by organic disease. Medical care can be more economical when discovery and control of adverse social factors is instituted. This is more important in the case of chronic disease such as tuberculosis.—Social Component in Medical Care, THORNTON, J., Columbia Univ. Press, 1938.

ANTHRACO-SILICOSIS

Statistics from White Haven Sanatorium, Pennsylvania, reveal that tuberculosis of the intestine was found in only 19 per cent of the cases where anthracosis and pulmonary tuberculosis were associated as contrasted to 51 per cent where the pulmonary tuberculosis was uncomplicated by silicosis. This may be due to the extreme fibrosis present in these cases preventing the spread of the tubercle bacilli. In early or moderately advanced cases of silicosis the rate of intestinal involvement is the same as in the cases which do not have silicosis.—CHARR, R., and COHEN, A. C., Am. Jour. Med. Science, 1938, 196.

SILVER PICRATE

Wyeth

Has shown a CONVINCING RECORD* OF EFFECTIVENESS in ACUTE ANTERIOR URETHRITIS

**due to *Neisseria gonorrhoeae* • *Trichomonas vaginalis*
*Monilia albicans***

Silver Picrate is a crystalline compound of silver in definite chemical combination with picric acid. Dosage form for use in anterior urethritis: Wyeth's Silver Picrate Crystals in an aqueous solution of 0.5 percent.

Supplied at all pharmacies in vials of 2 grams

Complete literature on Silver Picrate as used in genitourinary and gynecological practice will be mailed on request.

APICAL LUNG TUMORS OR SO-CALLED SUPERIOR PULMONARY SULCUS TUMORS*

HERMAN J. MOERSCH, M.D., H. CORWIN HINSHAW, M.D., Ph.D., and
IRA H. WILSON, M.D.
Rochester, Minnesota

PANCOAST,⁹ in 1924, called attention to a group of apical lung tumors which were associated with pain referred into the shoulder and arm of the affected side, and, in addition, to certain cervical sympathetic phenomena which produced a train of symptoms and findings suggestive of tumor of the spinal cord. Although, as early as 1838, the same group of findings had been described by Hare, little attention was paid to this interesting group of cases or to its possible etiologic significance. Pancoast was of the opinion that the tumors which give rise to this peculiar group of symptoms are pleural in origin, but he felt that, conceivably, the same condition might be produced by other conditions such as tumors of the spinal cord, meninges and neck, as well as by a cervical rib and vertebral neoplasm. Pancoast based his conclusions on a study of four cases, in three of which an exploratory surgical procedure was performed and in two of which biopsy was performed, but in none of which necropsy was performed.

In 1932,¹⁰ Pancoast applied the term "superior pulmonary sulcus tumor" to this symptom-complex and enumerated its essential features as follows: (1) homolateral pain around the shoulder and down the arm, (2) atrophy of the muscles of the arm and hand, (3) Horner's syndrome, and (4) roentgenographic evidence of a small homogeneous shadow at the extreme apex of the lung, with always a variable amount of destruction of ribs locally and often vertebral infiltration. He came to the conclusion that it must

be looked on as a distinct clinical entity. This conclusion was based on a review of his four original cases, one of which was discarded, and on four additional cases, in none of which biopsy or necropsy was performed. It is interesting to note that, without the addition of further material obtained for biopsy, he was now of the opinion that the tumors which produce this interesting condition were not pleural in origin, but rather were epithelial in origin and that most likely they originate from the fifth branchial arch. Owing to the absence of demonstrable metastasis, and owing to the absence of one or more of the characteristics that he had described, Pancoast dismissed the idea that the condition might be one of primary carcinoma of the bronchus or sarcoma of a rib.

A review of the literature reveals that the condition occurs infrequently, and that there exists considerable difference of opinion as to whether or not the condition can be looked on as a distinct clinical entity, or one of primary carcinoma of the bronchus. In order to determine, if possible, the exact nature of superior pulmonary sulcus tumor, a study is presented of all cases encountered at The Mayo Clinic during a period of ten years, from January, 1928, to December 31, 1937, inclusive, in which findings described by Pancoast as essential for such a diagnosis were encountered.

The comparative rarity of the condition was substantiated, in that only thirteen cases were encountered in which all the essential features of the disease were present. Four other cases are included in the study, as they possessed all the

*From the Department of Medicine (Moersch and Hinshaw) and The Mayo Foundation (Wilson—now residing in Worthington, Minnesota), Rochester, Minnesota.

features of the first group except for Horner's syndrome. A study of these latter four cases is of special interest, in our opinion, for it tends to disprove the contention that tumor of the superior pulmonary sulcus can be considered as a distinct clinical entity.

As in cases of primary carcinoma of the bronchus, tumor of the superior pulmonary sulcus was found to occur in the male more frequently than in the female; thirteen of our patients were males, and four were females. At no age does it appear that one is exempt from the disease. The youngest patient in our group was nineteen years of age, and the oldest seventy-two; the majority, however, were in middle age. The left apex was the favorite site of the tumor; it was involved in twelve cases. The right apex was involved in five cases.

Pain was by far the earliest and most annoying symptom. It usually begins near the shoulder and tends to spread down the arm and around the scapula, on the homolateral side. It is usually intermittent in character and generally is worse at night. Early in the course of the disease, especially before the development of Horner's syndrome on the same side, and before roentgenologic studies of the thorax have been made, the condition is often mistaken for "rheumatism," neuritis or even angina, and, when the pain is suspected of being of "rheumatic" origin, tonsillectomy for relief is not an uncommon event. The condition, as a rule, is rapidly progressive and disabling. Physical examination of the thorax is generally of very little value for the detection of a tumor in the lung early in the course of the disease, and the correct diagnosis may tax the diagnostic acumen of the most careful physician. Careful roentgenologic examination of the thorax is of utmost importance and is of very great aid in early diagnosis. However, Pancoast has pointed out the ease with which the early roentgenologic changes caused by the tumor may be overlooked.

Hemoptysis, which is such a frequent symptom in cases of primary carcinoma of the bronchus, occurs less frequently in association with tumor of the superior pulmonary sulcus. Only three of our seventeen patients related a history of expectoration of blood. Two of the patients had fixation of a vocal cord on the affected side, a condition which also was noted by Kelman and Schlezinger.

Tissue for microscopic examination was obtained in nine of the thirteen cases in which the characteristic findings of tumor of the superior pulmonary sulcus were present, and in three of the four cases in which Horner's syndrome was not present. In four of the cases, two from each of the aforementioned groups, respectively, necropsy was performed, and in all four cases findings were regarded as those of primary carcinoma of the bronchus with metastasis to other organs of the body. This latter observation is especially deserving of attention because Pancoast regarded such a finding as rare or not likely to occur. Microscopic examination of the tissue removed from the tumors was reported as squamous-cell carcinoma in three cases, and was not classified as to type in one of the cases in which Horner's syndrome was absent. In three of the thirteen typical cases, surgical exploration was performed. In each instance, the tumor was inoperable; evidence of invasion of the vertebræ or ribs was present. In two of the three cases, tissue was removed from the tumor, studied microscopically, and reported as adenocarcinoma, grade 4 (on the basis of 1 to 4), according to the Broders classification. In five other cases, biopsy was performed on supraclavicular lymph nodes overlying the apical tumor (four from the typical group and one from the atypical group), and of these five cases, four were cases of adenocarcinoma and one was a chondroma. This latter case will be described in detail.

It is not necessary to present all seventeen cases in detail. However, a few cases are given to illustrate the character of the lesion which we are describing, and to emphasize certain important features under consideration. Case 1 is typical of the group in which all the characteristic findings of superior pulmonary sulcus tumor were present.

Report of Cases

Case 1.—A white man, forty years of age, came to The Mayo Clinic for the first time in April, 1933; he complained of pain in the right shoulder and general weakness. The difficulty began nine months previously, soon after changing from a sedentary occupation to an active one. The difficulty was thought to be due to his change of work. The pain was sharp in character, constant in nature and definitely worse at night than during the day. The pain was of such severity that it interfered with rest and was associated with a loss of appetite and subsequently with loss of weight. Because of the character of the pain, a diagnosis of rheu-

matism was made elsewhere, and tonsillectomy was performed without benefit. The right arm gradually became weaker, and numbness and coldness developed in the second and third fingers of the right hand. At approximately the same time, drooping of the right eyelid and absence of sweating of the right side of the face were noted. Two weeks before coming under our care, the patient experienced a chill with fever and because of this a roentgenologic examination of the

months later at home as a result of massive pulmonary hemorrhage.

Pancoast was insistent on the presence of Horner's syndrome on the affected side, as essential for the diagnosis of a tumor of the superior pulmonary sulcus. On this basis, he refused to accept the cases of Henderson which were presented to prove that the condition could not be a distinct clinical entity. Pancoast failed to realize that Horner's syndrome took place only with advance of the apical tumor or lesion until the cervical sympathetic chain on the homolateral side was involved. In one of his own cases, he noted that Horner's syndrome appeared only late in the course of the disease. We are in agreement with Stein that the presence of Horner's syndrome is only a manifestation of the degree of spread of an apical tumor; in no way is it related to a specific type of tumor occurring in the thoracic inlet. This observation is based on a study of four of our cases in which were present all the characteristics of a tumor of the superior pulmonary sulcus, other than Horner's syndrome. In two of the cases necropsy was performed and a primary carcinoma of the apex of the lung was found; in every respect the tumor resembled that encountered at necropsy in the two cases in which Horner's syndrome was present. In an additional case, a lymph node was removed from the supraclavicular fossa overlying the tumor in the apex and was found to be adenocarcinoma. Case 2 is illustrative of this group, and the similarity to the first case reported is readily apparent.

Case 2.—A white man, twenty-eight years of age, came to The Mayo Clinic, for the first time, November 18, 1938; he complained of pain in the left shoulder and arm. The pain had begun four and a half months previously. It was constant in character and was aggravated by motion. There was associated numbness of the anteromedial surface of the forearm. The pain was of such severity that it interfered with sleep and appetite. A diagnosis of neuritis was made elsewhere, and the tonsils were removed without benefit. A month before coming to the clinic, a diagnosis of Pancoast tumor was made, and roentgen therapy was administered with relief of pain for a period of three weeks.

At the time of our examination, the patient's blood pressure was 134 mm. of mercury systolic, and 84 diastolic. The pulse rate was 84 per minute and the temperature was 99.4° F. (37.4° C.). The patient held his head inclined toward the left side and fullness was noted over the left supraclavicular region but

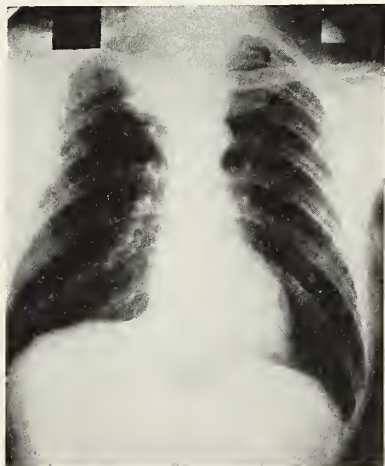

Fig. 1. Case 1. A typical case of superior pulmonary sulcus tumor.

thorax was performed; a shadow over the apex of the right lung was noted.

At the time of our examination, the patient appeared undernourished and was suffering with pain. Entophthalmia of the right eye was present, the right pupil was smaller than the left and a droop of the right lid with narrowing of the palpebral fissure was present (Horner's syndrome). There was fullness over the right supraclavicular region, a hard, nodular mass being present. There was a slight droop of the right shoulder. A slight degree of atrophy of the muscles of the right hand was noted. On percussion, dullness was elicited over the apex of the right lung, but otherwise the findings were essentially normal.

Roentgenologic examination of the thorax revealed a circumscribed shadow over the apex of the right lung. There was no apparent involvement of bone (Fig. 1). The laboratory tests, such as urinalysis, examination of the blood and flocculation tests, failed to reveal anything of diagnostic importance. The diagnosis of a tumor of the apex of the right lung (Pancoast type) was made. Roentgen therapy was administered and the patient was permitted to return home. He returned to the clinic again within a month and was without evidence of a change in symptoms or findings. An exploratory thoracotomy was performed May 26, 1933, and an inoperable carcinoma was found involving the posterior half of the apex of the right upper lobe of the lung with infiltration into the spine and ribs. The patient was permitted to return home and died five

definite lymph nodes were not palpable. The skin over the right shoulder was dusky in appearance from previous roentgen therapy. The strength of the left hand was not as great as that of the right hand. Lymph nodes were palpable in the left axilla. On percussion of the thorax, there was a slight increase

cinoma which apparently was bronchial in origin (Fig. 3).

The point frequently has been made as to whether the lesions that occur at the apex of the lung are primary in nature or are secondary to

Fig. 2. Case 2. A case of superior pulmonary sulcus tumor without Horner's syndrome.

Fig. 4. Case 3. Shadow over apex as well as at hilus.

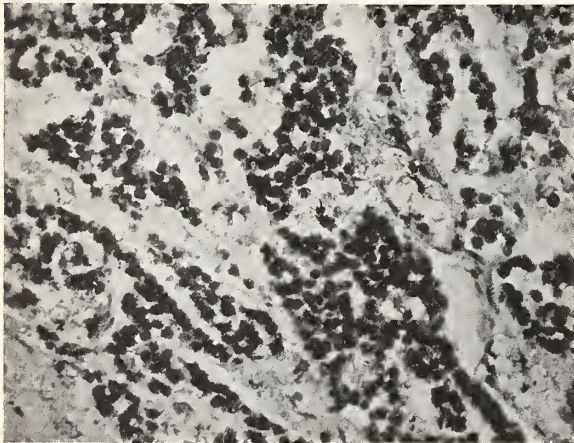

Fig. 3. Case 2. Small-cell carcinoma.

in dullness over the left apex posteriorly. There was no evidence of Horner's syndrome. Physical examination otherwise gave essentially negative findings.

Roentgenologic studies of the thorax revealed a dense shadow over the left apex of the lung (Fig. 2). The urinalysis, blood studies and blood flocculation tests gave negative results. A diagnosis of tumor of the thoracic inlet was made. Roentgen therapy was administered. In spite of this, the patient's health failed rapidly and he died at home six weeks later. Necropsy was performed, elsewhere, and tissue was sent to us for study which showed a very malignant small-cell car-

cinoma elsewhere, especially secondary to carcinoma of a bronchus close to the hilus. Metastatic lesions from other organs to the pulmonary apex have been reported by Evans, Frost and Wolpaw and others as causing the Pancoast type of tumor. The difficulty that may be experienced in determining whether an apical lesion is primary or not is well illustrated in Case 3.

Case 3.—A white man, fifty-two years of age, was admitted to The Mayo Clinic in September, 1937, because of pain in the left shoulder. The pain had appeared three months previously and was of such severity that it made the patient "dance." The pain gradually was projected down the left arm and into the left ring finger. Two months after the onset, an absence of sweating in the region of the left shoulder was noted. A diagnosis of tumor of the spinal cord was made elsewhere, and an operation was advised. At the time of our examination, the patient appeared to be in considerable distress. His blood pressure was 162 mm. of mercury systolic, and 100 diastolic; the pulse rate was 78 per minute and the temperature was 98.6° F. (37° C.). The skin over the left shoulder was dry and shiny and the temperature over the area of involvement was less than normal. Hyperesthesia was found along the medial and posterolateral surfaces of the right arm. Horner's syndrome was present and the left eye was involved. Lymph nodes were palpable in the left supraclavicular region and in the left axilla.

There was an absence of sweating over the left shoulder and arm and over the left half of the face, scalp and thorax.

Roentgenologic examination of the thorax (Fig. 4) showed a circumscribed shadow of the left apex and also of the left hilus; there was also evidence of in-

three years. Shortly before coming to the clinic he had noticed increased difficulty in swallowing, with a noticeable change in the quality of his voice.

On physical examination, a hard, firm mass measuring approximately 2 by 3 inches (5 by 7.5 cm.) was found in the left submaxillary and cervical regions.

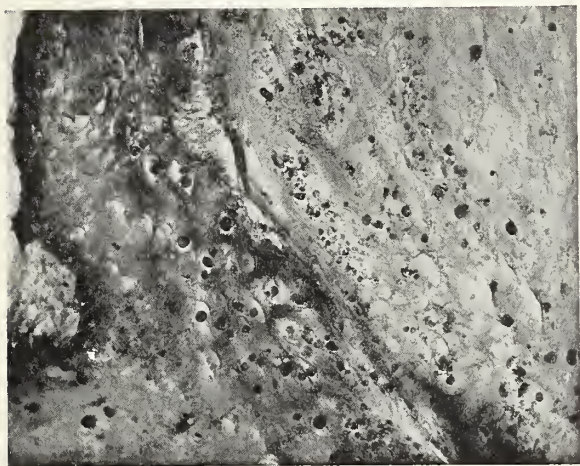

Fig. 5. Case 4. Degenerating chondroma.

vasion of the contiguous portion of the lateral part of the second thoracic vertebra and the second rib. The other laboratory tests failed to reveal anything of diagnostic importance. A diagnosis of primary carcinoma of the bronchus was made and roentgen therapy was administered in intensive doses. In spite of this, the patient's condition rapidly became worse, and he died at home four months later. Necropsy was performed elsewhere, and was reported to us as revealing primary carcinoma of the lung with metastasis to the liver.

Pancoast stated that the so-called superior pulmonary sulcus tumor was characterized by an absence of metastasis. Our experience has been at variance with this observation, however, and in accordance with that of Stein and Barton, namely, that metastasis occurs with great frequency. Nine of our patients had definite evidence of metastasis to lymph nodes, to the lung or to other organs of the body.

That lesions other than primary carcinoma of the bronchus may produce a picture similar to that described for a tumor of the superior pulmonary sulcus is well illustrated in Case 4.

Case 4.—A white man, forty-eight years of age, was seen by us for the first time in September, 1923. He complained chiefly of a swelling over the left side of the neck. This first appeared seven years previously and had especially increased in size during the last

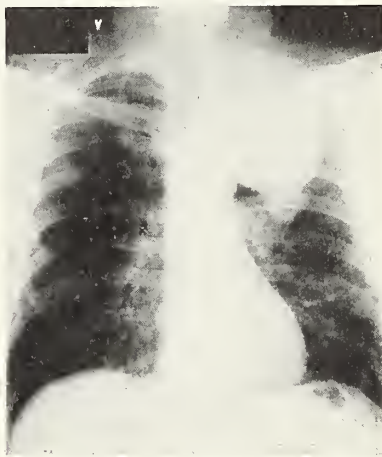

Fig. 6. Case 4. Tumor in left upper portion of the thorax.

The mass appeared attached to the hyoid bone. The mass produced a bulge into the lumen of the left wall of the pharynx, from the base of the tonsil down to the base of the tongue, pyriform fossa and along the posterior pharyngeal wall to the midline, obscuring the left half of the larynx and pushing the epiglottis over toward the right side. Roentgenologic examination of the lungs gave negative results. On September 20, 1923, the tumor was excised along with the left half of the hyoid bone. On microscopic examination, the tumor was reported as a degenerating chondroma (Fig. 5).

The patient returned to the clinic in November, 1931, because of pain in the left hand and thorax, numbness in the left forearm and hand, and a recurrence of the swelling in the lower submaxillary and cervical regions. The growth had developed during the past year. There was a slight but definite droop of the left eyelid. Roentgenologic examination of the thorax revealed a large tumor in the left upper portion of the thorax (Fig. 6) with multiple pulmonary metastatic lesions. In spite of roentgen therapy the patient failed rapidly and died soon afterward at home. Because necropsy was not carried out, some question may exist as to whether the recurrent growth was a new growth or a recurrence of the chondroma which had undergone malignant degeneration.

Comment

The prognosis for the patient who suffers from an apical pulmonary tumor is extremely grave. The great majority of such patients under our observation were dead within six months of the

time of our initial examination. Up to the present time, we have not found any form of treatment successful in dealing with the condition. In an occasional case, temporary relief was obtained through the use of roentgen therapy.

From a review of our experience we are forced to agree with Jacox, Steiner and Francis, Browder and DeVeer and others that the so-called superior pulmonary sulcus tumor cannot be a distinct clinical entity, and that it simply is indicative that a lesion situated in the apex of the lung which is in close proximity to certain nerves invades or compresses these nerves, giving rise to a characteristic train of symptoms designated by Pancoast as the superior pulmonary sulcus syndrome. The tumor that most commonly produces this symptom-complex is primary carcinoma of the bronchus. The term "superior pulmonary sulcus tumor" is not a justifiable term except when used to indicate only that the lesion or growth is limited to a distinct portion of the lung. We have seen the same symptom-complex occur when the growth is not situated in the apex, but in the hilus of the lung, and when tis-

sue could be removed for microscopic analysis and could be demonstrated to be primary carcinoma of the bronchus.

EARLY GASTRO-INTESTINAL CARCINOMA*

GEORGE EARL, M.D.

Saint Paul, Minnesota

CARCINOMA continues to climb toward top place as a recorded cause of death, having now reached second place. Of a total of 3,775 deaths from cancer in Minnesota in 1938, 1,928 were of the digestive tract and peritoneum. In the United States public health statistics for 1936, of the 146,613 deaths from carcinoma, 49,930 were recorded as gastro-intestinal. It is likely that gastro-intestinal cancer is more frequent than records show. Surgery undertaken for other diagnoses and postmortems on cases of undetermined diagnosis increasingly are revealing gastro-intestinal carcinomata as the primary site.

Early symptoms of gastro-intestinal cancer may be insidious and vague. When the patient comes with marked weight loss, secondary anemia, pain, a palpable mass, marked constipation with or without alternating diarrhea, and vom-

iting, we no longer have early carcinoma but an advanced stage.

It is in middle age and beyond that these cases most often arise, although no age is free. Beginning at the age of thirty-five, there was in Minnesota in 1937 a definite increase in incidence of cancer in each successive five years of age up to seventy, then a slight increase up to seventy-five, with a slight decrease in those living in the decade beyond. In judging age it is not years alone that count, but rather the physical age of the patient.

Just as in other diseases of insidious onset, for example, tuberculosis, we have in early gastro-intestinal carcinoma symptoms of tiredness, weakness, and slight weight loss. Sara M. Jordan, of the gastro-intestinal department of the Lahey Clinic, tells in the February 17, 1939, issue of the *Journal of the American Medical Association*, of two patients with complaints of

*Read before the Northern Minnesota Medical Association at Detroit Lakes, Minnesota, September 8, 1939.

tiredness and general run-down condition. They took extended trips, and on their return advanced carcinomata of the stomach were evident.

Cancer's early picture is not impressive. Christopher states, "A little indigestion in any patient over thirty years should be regarded seriously." Many urge that x-ray examination be made in every patient over forty-five years of age in whom "indigestion" has existed unrelieved, even though not treated more than a week. Moynihan points out a fallacy in even this, saying: "The improvement of symptoms during medical treatment in early cancer of the stomach is one of the causes of the high mortality of this disease."

Several writers have recently agreed that the early symptoms of gastric cancer are: (1) slight loss of appetite; (2) vague stomach consciousness as fullness or "gasiness" after meals; (3) slight, vague abdominal discomfort or pain; (4) hypochlorhydria; (5) occult blood in stool. They also noted that by the time any of the classical symptoms, as weight-loss, anemia, vomiting, and palpable tumor, appeared, it was often too late for curative surgical treatment. All emphasized that cancer of the stomach can mimic almost any gastro-intestinal disease. While benign ulcers of the stomach and duodenum usually make themselves known by very definite symptoms, carcinoma, the most serious of all stomach conditions, usually begins with very negligible symptoms.

Bleeding, of which the public is so conscious in urinary and genital conditions, is strangely often minimized in gastro-intestinal carcinoma. Blood in the vomitus is often ascribed to retching, and from the rectum to hemorrhoids. In indefinite histories where there is occult blood in the stool, its presence must be explained. While in gastro-intestinal carcinoma there may be no occult blood, and one must not be misled either by its presence or absence, yet persistent occult blood in the stools is a quite consistent finding in carcinoma of the gastro-intestinal tract. Too frequently the test is not used in patients who should be suspected of this lesion. It is simple and economical. Consideration must be given not only to the finding of blood, but also of pus and mucus. Such tests must be repeated within a relatively brief period.

Regarding examinations, it has been said that if, in examining a patient, you do not put your finger in the rectum you are apt "to put your

foot in it." Osler said that a specialist is one who makes rectal examinations. This brings up, of course, the question of hemorrhoids. Insistence is for sigmoidoscopic examination either previous to scheduling a hemorrhoidectomy or at the time of the hemorrhoidectomy when the patient has been prepared. Of the 49,300 gastro-intestinal carcinomata reported in the 1936 government statistics, 7,300 were within finger reach, and another 7,000 in the sigmoid, therefore within relatively easy visualization through the sigmoidoscope. Direct visualization of the stomach through the gastroscope is becoming of increasing importance in gastric diagnosis. Abdominal palpation can never be too carefully made, and often it will reveal important findings to the examining fingers. Examination of the patient in a standing position may bring an upper abdominal mass, not felt in the horizontal position, down to where it can be palpated.

The determination of the sedimentation rate is an increasingly common laboratory procedure. Increased rate may or may not be present in early carcinoma, depending on inflammation accompanying it. The presence of bile even in small amounts seems to delay greatly sedimentation.

Hypochlorhydria is of questionable value and is found both in cancerous and non-cancerous conditions, although frequently in cancerous conditions there is a lower hypochlorhydria. Lactic acid and also the Opler-Boas bacillus occur with cancerous and non-cancerous conditions in the presence of stasis.

X-ray examination is the most accurate method of studying gastro-intestinal carcinoma that cannot be visualized or biopsied. The ability of x-ray to detect early lesions is at times amazing. Lesions as small as 1 cm. in diameter have been found and, even in the absence of definite lesions, slight changes in the mucosal pattern with almost imperceptible interference with peristalsis may give strong presumptive evidence. We have the actual picture of such a probable diagnosis by an x-ray man seeing a very small lesion in the stomach that is not palpable to the operating surgeon, and yet, on the roentgenologist's insistence on opening the stomach, there can be found a very small beginning gastric carcinoma. On the other hand, good x-ray men will miss early lesions of carcinoma of the gastro-intestinal tract, especially at the cardiac end of the stomach, in the cecum, and to a lesser degree in the remain-

ing bowel, et cetera. In a suspected case, as with unexplained occult blood or in one in which no diagnosis has been definitely made, reray must be done in the hope of picking up a lesion previously missed. A gastro-intestinal examination and follow-up is never sufficient for colon elimination; x-ray of the colon must be insisted upon as a separate procedure.

In gastric ulcer which, on x-ray examination, has the appearance of being benign, the patient should be placed in bed on a very strict peptic ulcer therapy régime. If, in ten days or two weeks, the clinical symptoms disappear, blood is absent from the stool, and x-ray shows a decreasing size of the ulcer, it is fair to assume that the lesion is benign. The medical and diatetic treatment should be under careful x-ray observation until the lesion is absent at least six months. If there is not a progressive recession or if the lesion progresses under exact medical régime, prompt operation is indicated. Gastric cancer may show an ulcer area larger but shallower than that of a benign ulcer. Gastric cancer affects males about twice as frequently as females. Of all the organs of the body, considering both males and females, world statistics would indicate the stomach to be the organ most affected by cancer.

We must remember that:

1. In so-called "benign" gastric ulcers, as distinguished from duodenal, cancer should be suspected.

2. Every ulcer on the greater curvature should be considered malignant, no matter how innocent may be its appearance.

3. The larger the ulcer, the more likely is it malignant, but any gastric ulcer, regardless of size, is to be suspected of malignancy.

4. A carcinomatous ulcer may apparently heal temporarily on strict medical régime and disappear from x-ray visualization.

5. Never disregard positive x-ray diagnoses of malignancy, even though some of them may be wrong. No matter how innocent the appearance on the operating table, the roentgenologist has an advantage over the surgeon in that he sees the normal, functioning stomach and can observe its peristalsis.

6. A negative x-ray report is never wholly to be trusted as absolutely ruling out malignancy. The increasing impression is that even with "apparently benign" reported on a large sized gastric ulcer on the greater curvature of the stomach,

and to a lesser degree on the lesser curvature, clinical history if sufficiently long followed is apt to reveal the presence of carcinoma, and that such ulcers, if they do not rapidly and completely heal, should be considered malignant.

Carcinoma of the colon develops gradually. There may be occult blood, anemia, and gradually developing weakness for many months before medical advice is sought. Due to the difference in the anatomical relations, the pathological variety of growth, and the fluid state of the bowel content in the right colon as compared with the more solid content in the left colon, we may have a difference in symptoms. The tumors in the right colon are usually flat and do not encircle the bowel. The bowel is of larger caliber and more pliable, for which reason obstruction will seldom occur unless the cancer is located at the ileocecal area. We must always keep in mind the possibility of having a well advanced carcinoma of the right side of the colon without any evidence of constipation or obstruction. On the contrary, quite often a diarrhea occurs. In the left colon a scirrhus carcinoma of smaller size which encircles the bowel wall causes gradual obstruction of the bowel. Symptoms may be heaviness in the epigastrium, irregularity of defecation with a tendency to constipation, and, at times, alternating diarrhea. If a patient of middle age or older complains of a gradually developing constipation with or without intermittent diarrhea, when there has been no acute illness, change of diet or occupation, we should think of the possibility of a gradually developing carcinoma.

Often the striking feature of gastro-intestinal carcinoma is the advanced stage reached before the patient is aroused or before the case is diagnosed. Familiar examples are a gross lesion of the greater curvature of the stomach with widespread metastases, revealed probably in a gastro-intestinal x-ray for a routine or general examination; a gross lesion in the cecum palpable to the surgeon on examination and yet not having caused the patient any alarm; an apparently sudden obstructing picture of the bowels from a gross left colon growth in a patient who until then thought only of slight gastro-intestinal inconvenience; or a gross, markedly advanced recto-sigmoid malignancy in a patient with long-standing bleeding hemorrhoids and who is shocked to think there could be any other cause than the "piles" for increasing symptoms.

There is the experience, too, of operating for another diagnosis, probably an acute condition, and finding a gross malignancy somewhere in the gastro-intestinal tract which had seemingly given no symptoms to date. Increasingly, the public has been educated to, and the medical man is demanding, more careful consideration of other possibilities in the presence of a presumably simple diagnosis, as of cholecystitis with confirmatory x-ray findings. A thorough scrutiny of the gastro-intestinal tract will often reveal additional disease, such as a duodenal ulcer, and every once in a while an early malignancy of the stomach or bowel.

Of course the question of expense often arises: In the case of charity patients or of those well able to pay, there is no problem. But with the low income group, it will be asked if we are justified in demanding such complete examinations in patients of cancer age with indefinite symptoms. There are, however, many relatively inexpensive procedures available: rectal examination, sigmoidoscopic examination, careful histories bearing in mind the vagueness of early symptoms, and, of prime importance, more frequent stool examinations. Then, if any indications exist, insistence must be made on sufficient examination to prove the condition, and usually a way can be found.

Regarding treatment, chemical approach has, as yet, yielded nothing very definite. Freezing methods are now being experimented with. Electro-coagulation or heat cauterization have a place in treatment, especially in the rectum, and at times in the lower sigmoid. The knife, x-ray, and radium are still the instruments of choice. Of these methods, it is likely that there is most difference of opinion as to indications for x-ray treatment.

It is unfortunate that so common a lesion as gastro-intestinal carcinoma should generally be very resistive to radiation therapy. Carcinoma of the stomach is particularly resistive, and at most all that can be hoped for, even with intensive high voltage radiation, is slight palliation. Lymphosarcoma of the stomach is one malignancy which does respond well to radiation and, in rare instances, possibly a permanent arrest is attained. The adenocarcinomata of the small bowel respond as poorly to radiation as those of the stomach. The carcinomata of the colon, rectum, and anus show a decreasing resistance in this order, and

vary greatly from the most resistive to the most sensitive types. Those of the cecum, ascending and transverse colons, and of the greater portion of the descending colon, as a group are as resistive to radiation as those of the stomach and small bowel. Postoperative radiation directed to their gland bearing areas also is futile, as these extended lesions are particularly resistive. The carcinomata of the lower portion of the colon, including the sigmoid, respond more favorably to radiation, but on the whole, it gives rather poor results. Postoperative radiation to the gland bearing area of this group, however, is indicated.

Descending further in the large bowel to the rectal carcinomata, we find a much greater response to radiation, and these lesions offer a good opportunity for the surgeon and radiologist to coöperate in the attainment of good results. If surgical removal of the rectal carcinoma is possible, it is the method of choice and should be followed by intense radiation to the operative site and the regional glands. In some of these rectal lesions, it may be advisable to insert radium into the lesion, and this to be supported by external roentgen radiation. The sensitivity of the rectal carcinomata in general warrant the use of intensive radiation. The anal carcinoma, which is usually the squamous cell type, is the gastro-intestinal lesion most sensitive to radiation, and is easily treated with it. Cure of this lesion with radiation is the rule, and this constitutes the one really bright spot in radiation therapy of gastro-intestinal carcinoma.

An effort has been made to restate the fact that gastro-intestinal involvement constitutes by far the largest group of carcinomata, and yet it is here that diagnosis of cancer is often longest delayed. In other regions, the public has been made more conscious of early manifestations. We, as doctors, must educate the public to the fact that if early gastro-intestinal diagnosis of cancer is to be made, the patients must come to their family consultants, not with typical textbook symptoms, but because of such vague complaints as epigastric heaviness or discomfort, "dyspepsia," lessening of appetite, any stool change or irregularity of bowel movement persisting for more than two weeks, and any unexplained weakness, tiredness, or loss in weight. Until now any unusual discharge has been stressed to the public as an early sign of cancer, and this is, generally speaking,

true, as in such instances as an unusual discharge from a sore on the face, from the nose, or from the nipple. Blood has been especially emphasized as an early sign, and this is true with cancer of the bladder and kidney, as it is also true with an irregular or unusual discharge from the female organs. Certainly blood from the stomach or rectum is to be kept before the public as a sign of cancer, but it is of utmost importance that the public be informed that, unlike the urogenital tract, blood from the gastro-intestinal tract as observed by the lay person is not usually an early sign of cancer, but often a late sign.

We must not be misled by the fact that patients

with cancer of the gastro-intestinal tract will improve on a non-roughage diet and, with mineral oil added, feces will pass narrowing obstructive points. With any suggestive history, certain procedures become immediately necessary: digital rectal examination, careful abdominal palpation, and stool examinations. In early diagnosis of cancer today, the gastro-intestinal tract presents Problem Number One because of its high percentage among cancer conditions, because of its insidious early symptoms, and because, at times, of the treachery of its relatively long existence before giving gross manifestations.

RECURRENT MYXOSARCOMA OF THE RIGHT INGUINAL REGION

Report of Case

L. K. BUZZELLE, M.D., and R. B. TUDOR, M.D.
Minneapolis, Minnesota

MYXOSARCOMATA may occur in many locations. They are most frequent in the retro-peritoneal region, the muscular fasciæ of the thigh, the bladder, and the forearm. They may occur in almost any tissue of the body, where myxomatous tissue never is found normally in the adult. They have been described in the head, breast, spermatic cord, prostate, testicles, along the course of nerve bundles, and in the pleural cavity. The age incidence is six months to eighty-three years. Most of these tumors are in the age group from forty to sixty years.

The etiology of these tumors is controversial. They probably arise due to a metaplasia of connective tissue elements. A fundamental and permanent change in the growth characteristics of some type of connective tissue cell must be assumed. The type cell is the mucous connective tissue cell as found in the early embryo restricted almost exclusively to the umbilical cord. It is a fibroblast which secretes a homogeneous, semi-fluid, intercellular substance called mucin. In a myxosarcoma many of these cells are likely to be spindle shaped. The more definite the establishment of the tumor as a malignant neoplasm, the more cellular it tends to become. A surprisingly large percentage give a history of injury, often severe, at the site of the subsequent appearance of the tumor.

Myxosarcomata of the inguinal region or thigh occur most often in the soft parts but may be attached to the periosteum of the bone.

Myxosarcomata of the thigh usually begin as a small fibrous swelling which persists and after a period of months or years suddenly begins to grow rapidly. They usually develop insidiously. Unless the tumor invades the nerves, there are no symptoms. These tumors do not metastasize early.

On physical examination the tumor appears as a large round or oval swelling. It is tough but not hard to the touch. There are no areas of fluctuation. The outline is usually not regular but contains many projections some distance from the main tumor mass. The size may vary a great deal. A myxosarcoma weighing thirty-two kilograms has been reported.

Myxosarcomata usually form lobulated or polypoid masses which may or may not be sharply demarcated and encapsulated. On section they often appear translucent, gelatinous, or colorless, but are sometimes grayish, yellowish, or reddish in part. The myxomatous portions are seen at the growing edge of the tumors. The central portions tend to become more cellular. The myxosarcomata are usually sufficiently vascular to assure an adequate blood supply to all parts. Necrosis in these tumors is observed in the more cellular parts, never in the advancing edge.

Myxosarcoma is a highly malignant tumor responding only occasionally to recognized forms of therapy. The treatment of these tumors is surgical. As a group the myxosarcomata are resistant to radiation therapy. After surgical removal these tumors are prone to recur locally. Metastases to the abdomen, lungs, vertebræ, and kidneys are quite common late in the disease. Metastases are frequently much more cellular than the parent growth. The mucoid or gelatinous property may be entirely lost in the metastases. The majority of deaths occur during the first year after treatment has been instituted.

Case Report

A white boy, ten years of age, came to us on December 17, 1938, complaining of a swelling in the right inguinal region. There had been a small, hard mass in the right inguinal region since 1930. One of us (Dr. B.) saw the patient in 1936, when a mass a centimeter in diameter was palpated below the right inguinal ligament. Surgical removal was advised at that time but was refused. The tumor did not seem to be getting any larger until January, 1937, when it began to increase in size. There was no history of injury before this phenomenon occurred.

The patient complained of some difficulty in walking and riding his bicycle because of the large size of the tumor, but these were the only complaints referable to the tumor. There was no pain. He had had a troublesome enuresis since infancy but otherwise had no urinary complaints. His bowel movements were normal. He felt well. There was no weight loss.

The urine, on examination, was normal. His blood morphology was also normal.

Examination revealed a large tough mass 3 by 4 inches in the right inguinal region, extending into the thigh and scrotum. It was not tender. It was not adherent to the skin, which could be moved freely over the tumor. The testicle could be palpated in the scrotum discrete from the tumor mass. No areas of fluctuation were felt.

On December 19, 1938, with the patient under ether anesthesia, the mass was exposed by an incision over the inguinal ligament extending into the scrotum. The capsule of the tumor was intimately connected to the surrounding subcutaneous tissue and fascia. The main body of the mass was around the saphenous vein at the fossa ovalis. The testicle was not adherent to the tumor nor was the spermatic cord involved in the tumor. There was apparently no invasion of the deep fascia of the leg or of the inguinal canal.

The saphenous vein was ligated at the fossa ovalis, and the tumor was removed by blunt dissection from the surrounding tissue. The fascia of the thigh was sutured to the fascia of the external oblique muscle, a Penrose drain was inserted in the wound, and the skin was approximated with Michel clips.

The tumor measured 10 by 12 centimeters in diameter. Grossly the tumor was grayish, very fibrous, and a cut section was quite slimy. The mass was split up into many compartments by fibrous trabeculae. Microscopic examination revealed a typical myxosarcoma.

Convalescence was uneventful and the patient was discharged on December 23, 1938.

In March, 1939, the patient was again seen, with a small two centimeter mass in the inguinal scar. On removal this growth exhibited essentially the same structure as the parent tumor.

The boy is still well and at present no metastases can be detected.

ADENOMYOMATA

WALTER G. BENJAMIN, M.D.

Pipestone, Minnesota

"An adenomyoma is a tumor, usually pelvic, found in, about or adjunct to the uterus, made up of connective tissue, smooth muscle and gland elements derived from uterine mucosa. The uterus, itself the commonest seat, is also undoubtedly the focus and source of dissemination of this growth, which is located within a limited radius at some point from the umbilicus down."—HOWARD KELLY.

ENDOMETRIOMATA are usually considered as belonging to the same class of tumors as adenomyomata—the essential characteristics of each being their content of epithelium resembling

uterine or tubal mucosa which responds to the stimulus of menstruation and pregnancy. MacCarty states, "an adenomyoma is any tumor in which glands and muscle play a neoplastic part and may presumably occur wherever these tissues exist in close proximity." Endometriomata, however, presumably come from transplantation of endometrial cells by way of the fallopian tubes onto pelvic peritoneum and do not contain muscular elements as a rule. However, most writers use the terms adenomyomata and endometriomata interchangeably and we shall do so in this discussion.

*Read before the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 1, 1939.

Theories of Origin

Sampson's theory is that commonly held today as best explaining the origin and pathogenesis of endometrioma. He has shown that wherever misplaced endometrial tissue is found, its histologic structure is identical with uterine mucosa

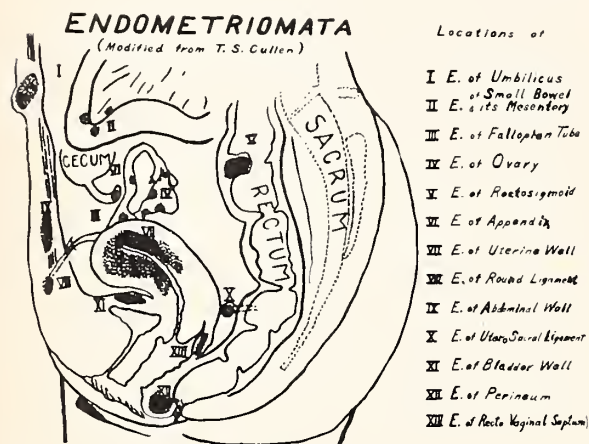

Fig. 1.

and it responds in like manner to physiological stimuli (i.e., ovarian hormones) in its reaction to menstruation, pregnancy and the menopause. According to this theory, blood and detached endometrial tissue from the uterus is regurgitated from the fallopian tubes into the pelvic cavity and results in endometrial transplants onto pelvic peritoneum—probably most often onto the ovary, primarily on account of its close anatomic relationship to the fimbriated end of the tube.

The ovary then often acts as the incubator for the endometrial cells. The so-called "chocolate cyst" develops, perforates and spills its contents, carrying endometrial particles to implant on other organs such as the abdominal wall, recto sigmoid, round and broad ligaments, etc.

Cullen in his excellent monograph in 1908 showed that many adenomyomas of the uterus had direct connection between the endometrial elements of the tumor and the endometrium of the uterine cavity.

Several other theories may be mentioned but they either are not accepted today or could conceivably account for only an occasional case. Von Recklinghausen in 1896 held that the epithelial element of adenomyomatous tumors arose from portions of the Wolffian body which had become detached during fetal life. Iwanoff suggested that endometriomata are formed by downgrowths

of the peritoneum, which has undergone metaplasia and become converted from a flattened to a columnar epithelium resembling endometrium as a result of chronic inflammation. The Mullerian theory attributes some endometriomas to the inclusion of Mullerian rests, especially in the ovary.

Endometrial transplants, especially to the abdominal wall, may also come from operation on the uterus or tubes. Several such cases have been reported after hysterotomy of the pregnant uterus, ventral suspension, etc. Lemon and Mahle of the Mayo Clinic report nine such cases of adenomyomata of the abdominal wall following various types of pelvic operations (not including cesarian section).

Frequency, Varieties and Location of Adenomyomata

There are three main varieties of adenomyomata of the uterus corresponding very much to the usual classification of fibromyomata of the uterus.

1. *Diffuse Uterine Adenomyomata*.—These are a part of the uterine wall, not demarcated or encapsulated as are fibromyomata. The uterus may be two or three times the normal size but the normal outline of the uterus is retained, although it may be somewhat irregular. On section, homogeneous translucent areas resembling mucous membrane may be seen scattered through a thickened coarsely striated portion of the wall. These areas may be brownish in color due to extravasated menstrual blood.

2. *Subperitoneal and Intraligamentous Adenomyomata*.—These are peripheral growths, having their origin in the uterus and growing outward into the broad ligament or subperitoneally. They may become pedunculated, very large and cystic, being filled with chocolate colored fluid (blood extravasated from the menstrual-like function of the endometrial lining).

3. *Submucous Adenomyomata*.—These are diffuse growths which have grown inward, become polypoid and projected into the uterine cavity and often through the cervix into the vagina.

Ovarian Adenomyomata or Endometriomata

"Chocolate cysts" of the ovary are perforating endometrial ovarian cysts filled with chocolate

colored material due to old hemorrhage. These occur during the menstrual life of the patient. They are usually small, 2 to 4 cm. in diameter, but may be as large as 15 cm. in diameter. They are usually densely adherent to surrounding structures, the result of perforations, proliferation and extension of endometrial cells and also often due to a low grade inflammatory reaction.

In addition to these more or less primary sites of adenomyomata in the uterus itself and in the ovary, lesions may be found as secondary growths or implants in the following structures: tubes, round ligaments, broad ligaments, recto-sigmoid, utero-sacral ligaments, recto-vaginal septum, abdominal wall (mostly following operations), bladder wall, etc.

These tumors may be quite benign or may prove fatal by exerting pressure on important organs, or they may obstruct a ureter or bowel. They may also develop malignant changes.

ANATOMIC LOCATION OF LESIONS

Location	Number	Per cent of Patients*
Uterus	618	69.9
Cervix	22	2.5
Ovary (probably not complete)	120	13.6
Rectovaginal septum	27	3.0
Ligaments of uterus	22	2.5
Sigmoid, rectosigmoid or rectum	24	2.7
Pelvic peritoneum	44	5.0
Vaginal wall	17	1.9
Fallopian tube	27	3.0
Umbilicus	6	0.7
Ileum	2	0.2
Appendix	1	0.1
Bladder	2	0.2
Diffuse	108	12.2

*More than one organ affected. The total, therefore, does not add to 100 per cent. (Counsellor, Mayo Clinic).

Gonzalez reports that endometriosis is twenty times less frequent in the fallopian tube than in the ovary. Sampson found endometriosis in 43 per cent of abdominal operations on women between the ages of thirty and fifty. Many showed such slight involvement that they produced no symptoms. Dougal states that for every 100 cases of uterine fibroids there are twenty-five cases of external endometriosis (i.e. endometriosis outside the uterus) and six cases of internal endometriosis (the endometrioma a part of the uterus). He also states that the ovaries are involved in 70 per cent of the cases and gives the following locations of the endometrial tumors in his se-

ries of 241 cases: ovaries—103 cases; recto-vaginal septum—62 cases; recto-vaginal septum and ovaries—71 cases. The five remaining cases showed other locations. Dougal estimates that 10 per cent of all laparotomies done by him during an eleven and a half year period had external endometriosis. In Seitz' series of sixty-five cases the endometrial tumors were in the following locations: ovary—23; uterus—19; tubes—8; Douglas pouch—4; rectum—4; parietal and visceral peritoneum—4; laparotomy wounds—4; urinary bladder—3.

Counsellor of the Mayo Clinic gave a very comprehensive summary of 884 patients with endometriosis seen at the Clinic from 1923 to 1937. These cases include uterine adenomyomata within and without the uterus and are listed in the accompanying table.

Symptomatology and Diagnosis

Adenomyomata are very interesting tumors. They produce in the uterus "a periodical increased tension due to the swelling of the various islets of mucosa, causing an intense grinding pain and a feeling of distention and dysmenorrhea as the effused blood is added to previous accumulations." If the tumor is unilateral, outside the uterus, in the broad ligament or ovary, this type of pain is unilateral.

Diagnosis must usually be made at operation or by the pathologist although a careful history and clinical examination may arouse suspicion. A patient with extremely painful periods and a hard and diffusely enlarged globoid uterus may have an adenomyoma of the uterus. Any firm tumor in the inguinal canal which enlarges and becomes painful during the menstrual period is likely an adenomyoma of the round ligament. Lockyer states, "We must regard an adenomyoma as a hemorrhagic and painful structure which is found in bad company, its intimate associates being adnexal tumors and pelvic peritonitis, parametritis and infiltration into bowel, whilst it can claim caseating tubercle, carcinoma and sarcoma as casual acquaintances."

"Endometriosis is a disease of the age of ovarian activity, for its development and progress are dependent on the same ovarian hormone that causes normal menstrual changes in the uterine endometrium" (Crossen).

Keene and Kimbrough suggest that the correct interpretation of the clinical picture as a whole

would point often to a correct diagnosis. Such a symptom-complex would be about as follows:

1. Age between twenty-five and the menopause.
2. Sterility—relative or absolute.
3. Abnormal menstruation—usually menorrhagia.
4. Dysmenorrhea of acquired type.
5. Dyspareunia
6. Sacral backache
7. Intermenstrual lower abdominal pain with increased discomfort at the time of menstruation.
8. Pain in the rectum or bladder which bears a direct relationship to menstruation.

In endometriosis we often find fixation and induration in the pelvis without evident cause, without a history of infection and with no pus present. Often a retroverted irregularly enlarged uterus fixed in the cul-de-sac without evident cause harbors an endometrioma or is attached by external endometriomata to the peritoneum of the cul-de-sac.

Treatment

Authorities differ widely as to treatment: whether it should be conservative or radical. Practically all opinion is agreed on Sampson's theory, that the endometrium is the main and only important element of adenomyomas or endometriomas and that this responds as does the uterine endometrium to ovarian hormone stimulation. It would seem to follow definitely, therefore, that to destroy the tendency of endometriomas to "menstruate," become engorged, proliferate and adhere to other organs, that the ovarian function must be removed. There may be exceptions to this rule. Perhaps, too, some endometriomata continue to grow after bilateral oöphorectomy because aberrant ovarian tissue still secretes its ovarian hormone. Conservative surgical methods have been used to try to conserve the menstrual and reproductive functions in women in the younger age group, especially when the lesions are fairly easily accessible as in the adnexal regions with possibly some peritoneal transplants. Many adenomyomata, especially the external type, atrophy following ablation of ovarian function by oöphorectomy, or destruction of ovarian function by radium or roentgen rays. In

Counsellors' series of 884 cases, 162 were treated by conservative procedure, 701 by radical procedures and twenty-one by radium and roentgen ray. In so-called internal or uterine adenomyomata, especially if the patient is near or past the menopause, hysterectomy is usually advisable as some of these lesions will become malignant.

Dougal states that true conservative treatment was possible in only 10 per cent of his series of 262 cases. He further states, "The average person's reaction to these figures will probably be one of surprise that so many radical operations were considered necessary, but it must be remembered that to be successful, conservative treatment should not only conserve function but also cure the disease. Many keen advocates of conservative surgery are likely to forget this in their anxiety to preserve the reproductive function."

Operative Findings and Pathology

Typical findings have been so well described by Novak that I quote as follows:

"The surgeon on opening the abdomen and exposing the pelvic organs finds a small adherent mass in one or both sides of the pelvis, usually attached to the posterior surface of the uterus quite low down. On loosening these adhesions to rotate the adnexa into the field of operation, there is a gush of chocolate colored or dark rusty-looking fluid, and this should at once make him think of endometriosis. On examining the ovary he will see a small cyst with a dark hemorrhagic lining, which has been opened in bringing up the adherent adnexa. The cyst may be only a centimeter or so in diameter, and is rarely larger than a hen's egg. The tube is usually quite normal, with patent fimbriated extremity, though it may be surrounded by peritoneal adhesions. On carefully inspecting, by good light, the depths of the pelvis, he will frequently see a number of rather puckered hemorrhagic areas of dark bluish color, in one or both uterosacral ligaments, and similar areas may be seen on the anterior surface of the sigmoid or rectum, or elsewhere in the pelvis.

"This, then, is a very typical picture, but it may present all sorts of degrees and variations. In not a few very mild cases the adnexa may at first sight seem quite normal, but on close inspection of the ovaries one may see a number of reddish-pink, fibrin-like areas representing tiny endometrial islands or 'implants.' Or one may see hemorrhagic areas, similar to those described, in the cul-de-sac or elsewhere, even when the ovaries seem entirely normal.

"At the other extreme are cases in which the pelvis may be filled with a 'frozen' mass, consisting of an adenomyomatous uterus, firmly adherent adnexa, and bilateral endometrial cysts, and extensive endometrial invasion of the rectal or sigmoidal wall. In fact, the bowel may be so enormously infiltrated as to simulate

malignancy, or to produce complete obstruction, while at times the invading endometrium may push far down in the rectovaginal septum.”⁸

Endometriomata in the ovary or implants elsewhere show grossly as “blood tumors”—that is, they show cavitations which contain dark blood from old and continued menstrual-like extravasations. They are somewhat cystic and show surrounding inflammatory or infiltrative reaction, whether in the abdominal wall or ovary. The most typical of these is the so-called “chocolate cyst of the ovary.” In the uterine wall translucent areas, brownish in color due to extravasated menstrual blood, are often present and are typical of adenomyomata of the uterus. The smaller peritoneal endometrial implants are rarely over 0.5 cm. in diameter and show up as bluish or brownish-red cysts, often with puckering of the tissues about them. Similar endometrial tumors in the navel, laparotomy scars, or the blue dome cysts of the posterior vaginal vault all show similar coloration and on rupture discharge old blood.

I have selected two cases illustrating some of the different types of adenomyoma and the reactions which lead to distinct problems in the management of this disease.

Case 1.—This patient, female, single, aged 33, was first seen in December, 1930, with a complaint of gradually increasing pain the past six months through the lower abdomen, especially in the right lower quadrant, pain being increased by jars and jolts, riding, stooping, etc. The pain radiated to the sacrum and the past four or five months she had had almost constant pain in the rectum, which was worse on defecation. She had urinary frequency and bearing down but no nocturia. All the above symptoms were much aggravated at the menstrual periods, which were regular and scanty and of about five days duration. She has had severe dysmenorrhea for several years, the pains beginning five to seven days before and continuing throughout the period.

Her general health has never been good. She had had recurring sinus infections, indefinite indigestion, migraine, and had always been underweight.

Examination.—General examination was essentially negative, except that there was a tenderness over the lower abdomen, especially in the right lower quadrant. Bimanual pelvic examination showed the uterus to be retroverted, irregular and apparently continuous with and fixed to a tender irregular mass in the right adnexa and cul-de-sac.

Diagnosis.—The preoperative diagnosis was probably fibromyoma of the uterus.

Operation.—At operation, December, 1930, a chroni-

cally inflamed appendix, bound down in adhesions medial to the cecum, was removed. The uterus was of normal size, retroverted and fixed to a cystic tumor 12 centimeters in diameter, which filled the right pelvis. The tumor originated from and had destroyed the right ovary and was fixed to the broad ligament and other structures. On freeing the tumor, it ruptured, spilling a chocolate colored slightly viscid fluid. The cyst wall was dissected free and removed and the bleeding from the raw surfaces controlled. A temporary type of suspension of the uterus was done to keep it from falling back into the cul-de-sac.

The patient remained free of pelvic symptoms and in fair general health until December, 1931, a year following operation, when she had severe knife-like pains across the lower abdomen, mostly in the right lower quadrant, eight or ten times each day of her menstrual period, with much bearing down. The pelvis was essentially normal.

In June, 1932, there was a recurrence of pelvic and referred pains much like she had had before her operation. Periods recurred about every two weeks, lasting about six days with an increased amount of flow, clots, and severe pain so that the patient had to spend three days of each period in bed. She developed increased lumbo-sacral backache and pressure on the rectum, which was made worse by walking, riding in the car, etc. She had fever and tachycardia for long periods.

Examination showed a tender indurated area five centimeters in diameter in the suprapubic portion of the old operative scar. Bimanual examination showed the fundus fixed in retroversion and irregular pea-sized nodules were present in the cul-de-sac, across the front of and adherent to the rectum but not fixed to or eroding into the rectal mucosa. This condition continued to progress slowly with the nodules in the cul-de-sac becoming gradually larger and more confluent. The suprapubic mass became more tender at each menstrual period and finally became bluish in color and discharged a dark bloody material through a suprapubic sinus most of the time but in increased amounts at menstrual periods. A biopsy of a specimen of the suprapubic mass, October, 1933, was diagnosed as (1) endometrioma and (2) low grade subacute infection by Dr. E. T. Bell.

At operation, June, 1934, we resected the section of the suprapubic abdominal wall involved in the adenomyomatous lesion (3 x 4 x 2 cm.)

There was no evidence of ovarian tissue in the right pelvis. Confluent pinkish nodules involved the cul-de-sac and extended across the rectum and posterior aspects of the broad ligaments. The left ovary was irregularly enlarged to three times its normal size, showed purplish areas and was fused with the left tube and broad ligament. The fundus showed small subserous nodules. We removed the left ovary and the outer two-thirds of the left tube, together with the involved posterior aspect of the left broad ligament. Dr. E. T. Bell made a diagnosis of endometrioma of the abdominal wall tumor and left ovary. The wound was closed without drainage and radium needles were placed in the abdominal wall at the site of the tumor.

GREETINGS FROM THE ALUMNI--HAGEN

Her convalescence was uneventful and we were able to follow the gradual subsidence and finally the disappearance of the nodules and the induration in the pelvis. There has been no recurrence of the abdominal wall or pelvic tumors. The patient had mild menopausal symptoms for two to three years and no menstrual flow following the last operation. Her general health has continued good except for migraine.

Case 2.—This patient, female, married, aged 63, was first seen March 21, 1931.

Past History.—In 1906 the left tube had been removed for tubal pregnancy. This was followed by a postoperative rupture which was repaired in 1910 and this was followed by a second postoperative rupture which was repaired in 1925 at the University Hospital. Menopause had occurred at forty-eight.

Present Illness.—She had profuse vaginal bleeding in September, 1930, and passed several tissue-like masses. She had spotting from then until January, 1931, and had a second moderately severe hemorrhage March 8, 1931, and passed a "tissue mass the size of a kidney" (description as given by patient suggested a pedunculated submucous adenomyoma or fibromyoma) and slight bleeding continued and became profuse March 20, 1931, requiring packing. Examination of the pelvis showed a patulous elongated cervix with a stump of tissue projecting through the os suggestive of the pedicle of a submucous fibroid. The fundus was the size of a small to medium grapefruit.

Thorough curettage was done and Dr. E. T. Bell reported the tissue to be a submucous adenomyoma. Heavy radium dosage was given following dilatation and curettage on four different occasions, from March, 1931, to February, 1932, but with only temporary help. The tissue removed on curettements was pale pink and soft, with some gelatinous areas. The specimen sub-

mitted to Dr. Bell, February, 1932, was diagnosed as myosarcoma.

It was realized she would be a very poor surgical risk on account of her age, weight (260 pounds), hypertension (260/138), but since the tumor did not respond well to further radium, operation was done, June 9, 1932, under combined spinal and general anesthesia. The uterus was one and one-half times the normal size and its peritoneal surface was irregular and indurated. There was considerable thickening and induration in each broad ligament adjacent to the uterus. No definite glandular metastasis were found outside of the pelvis. The tubes and ovaries were atrophic. A total hysterectomy was performed and the patient had an uneventful recovery.

A recurrent mass was treated by radium needles, October 3, 1932, but the patient died later, elsewhere.

GREETINGS FROM THE ALUMNI*

O. J. HAGEN, A.M., M.D., F.A.C.S.

Moorhead, Minnesota

MR. Toastmaster, President Ford, Members of the Board of Regents, distinguished guests and ambassadors from afar, members of the faculty of medicine, alumni, and friends of the University and the Medical School:

So many impressive commemorative addresses and valuable contributions from distinguished members of the medical profession and representatives of the allied sciences have been given during these two days that towards the celebration's close no one can quite hope to measure up to the

task assigned, and that is the thing that painfully distresses me personally at this otherwise enamoring hour. Surgeon General Parran's statesman-like and masterly presentation at yesterday's Convocation, Dean Diehl's, President Ford's, Governor Stassen's and Dr. Carlson's addresses of last night were masterpieces worthy of remembrance. They should be sealed in caskets of gold to be opened and the contributions read at the 100th anniversary. None of you, not even I, will be present to hear and enjoy them—but they will testify eloquently to the fact that there were Giants in the Earth in our day who were in the

*Banquet address on the occasion of the 50th Anniversary of the Founding of the University of Minnesota Medical School, October 13, 1939.

trenches of our social order battling for a better day. I was present, as was Dr. Ford, at the Harvard tercentenary, and we came to realize how much the voices out of the past mean on such an occasion. Caskets sealed 100 years were opened and we listened breathlessly as they read what they contained.

On an occasion like this when I am not speaking for myself alone but representing upon this program a lordly group—the alumni of the medical school—numbered among whom are some of the world's great surgeons and medical men, what disconcerts me is that I feel inadequate to the task, and that I may unwittingly say the wrong thing as a little old lady friend of mine in Moorhead once did. Her neighbor lady had lost her husband. He had taken the vulgar way out by hanging himself in the attic. In such a situation it is trying to know just what to say in consolation and the little old lady worried about it. But she decided to go and when her daughter returned she found her mother dressed up and ready. Said her daughter, "Now you know, Mother, you talk too much anyway and you get yourself into trouble." She resented the allegation and retorted, "I guess I know what I am doing. It has stopped raining and I can talk about the weather, can't I, and that has certainly nothing to do with her husband hanging himself in the attic." With that retort she started over across the back lot. Fortunately, she found her friend standing on the back stoop. She said, "Good morning, Mrs. Jackson, fine day out." The bereaved friend replied, "I should say not—look at my washing hanging out there on the line—the clothes are not dry yet." "Well, Mrs. Jackson, I shouldn't think you would have such a hard time getting your clothes dry—you have such a big attic to hang things in."

But I certainly cannot be saying "the wrong thing" when I venture the assertion that never before has the campus of the University entertained so many distinguished medical men, so many chemists, physiologists, biologists at one and the same time. These latter—allies of the profession—have furnished the modern reconstructed temple of medicine not only the foundation stones upon which it is rebuilt but the chemist and the physicist among them have provided it with the armamentaria by which it is able to carry on its impressive warfare against disease. Thank God that in the re-

public of science and medicine there are no tariff barriers, no embargoes, no "black-outs." In the warfare against disease, the chemist has given the profession the anesthetics, the antiseptics, the vitamins, radium, the serums, the vaccines, the salvarsans and the sulfanilamides. The physicists have given us the x-ray, the spectroscope, the ultra-microscope. Together they have by their speculative minds penetrated the universe of the atom and revealed much of its mystery. Subtract their important contributions and scientific medicine will still be in its infancy. So we are happy and grateful that distinguished representatives of all these allies were invited to this celebration and have honored us by their presence and their inspiration.

So we are glad for anniversaries because they are timekeepers of progress. To those who are directly connected with such an event, they become occasions for appraisal of what the years have meant in terms of achievement, occasions for refreshing the minds regarding the historical background of the venture, for recalling the names of those that gave it impetus and carried on in faith and sacrifice. They are occasions too for renewing friendships among those connected in one way or another with it, and, surely occasions for reminding one another of the obligations in relationship to it. Then, too, it would be an unworthy discipleship that would not on such an occasion pause to envision the future and fail to re-dedicate themselves to the venture's continued nurture and development. Institutions worth the survival grow in proportion as they are buttressed by the spirit that founded them and by the faith and genius of those that come after.

Medicine is an ancient Guild. To its honor let it be recorded on this 50th anniversary that it has built the one great republic that has come out of a dark distant past to withstand all storms and to grow into an efficient human agency dedicated to the high service of man's welfare.

Tonight I come to you representing the 3,600 and more alumni of the University of Minnesota Medical School—the living and the dead. I am here to bring to this distinguished assemblage, their greetings and their cheers. We, as alumni, salute tonight the institution's distinguished past. We entertain the fond hope that in the second half century its achievements may be even greater, and that there may be vouchsafed for it a

continued wise leadership, buttressed by the highest scholarship and the most dynamic teaching power medical science and practice afford.

Minnesota is a proud state—for more reasons than one. I could enlarge upon this subject but it would consume several days. But one of its chiefest glories lies in the medical men it has produced. But yesterday we committed the mortality of two of them to the good earth and the immortality of their spirits to the memory of a grieving world. They were Minnesota-born and their names were lovingly known as Dr. Will and Dr. Charlie. So great were those Minnesotans, that eight years ago they were denominated among the seven greatest personages in their generation—the world over. Into this amazing half century they moved in, hand in hand, to write the most thrilling chapter in all the history of medicine. To their door the world made a beaten path though they lived in a forest. By their high performance they perfused medical practice with such incandescence in this state and the world as to light a pathway across it that will illumine it for centuries to come. They left lights flashing when and where they fell, and the alumni of Minnesota bow tonight in reverence and gratitude not only for the inspiration they gave but also for the monumental legacy they left their native state in the Mayo Medical Research Foundation they created that the profession might acquire a greater competence in the endless battle against disease. That is why I said that Minnesota is a proud state.

We would be recreant to a duty we owe did we fail as alumni upon this occasion to pay tribute to the then President of the University, Cyrus Northrop, whose memory is to me a perpetual inspiration, and to the great Board of Regents of those early days, who made the medical department a tangible and intangible part of the University of Minnesota. It was their vision, their faith, and their courage that created the medical school. They built more greatly than they knew, as most pioneers often do for their generation. We name tonight in reverence its successive deans: Millard, Ritchie, Westbrook, Lyon, Scammon—all but one now gone to his reward; not only to them this adulation but also gratitude to those early medical faculties that gave to the institution so much of faithful and impressive service. Grateful too are we to you, Dean Diehl, to whom but a few years ago was

tossed the flaming torch; yours is the responsibility and privilege of carrying on—to the end that from out of these medical halls may continue to go out highly trained human products worthy of a great profession. Somehow, we alumni feel just a little chestier when our Alma Mater receives trophies at its altars from the world's battle fields of endeavor of those who once were here. We note with pride your auspicious beginning and we look forward in the hope that the noonday of your reign "may keep the promise of its morn."

With you, President Ford, rests the heavy responsibility of breathing the breath of life into this great academic and professional aggregation of colleges—the job of coördinating the various departments that all may flower into deepest hues according to their kind. This university whose head you are is the sanctuary of the inner life of this great commonwealth. I know you will guard its sacred prerogative of academic freedom as is guarded the tomb of the Unknown Soldier in Arlington. Let no sinister hands ever pull it down from the high place it occupies in the intellectual firmament of the world.

A medical school linked intimately with a great university is twice blessed, as Dr. Parran emphasized in his convocation address yesterday, and we alumni appreciate the *Unitas Fratrum*. The advantages of this most natural union are manifold and reciprocal. It is a spendthrift state that educates but one part of a man and sends him out into its social order with but cunning-niggard of the human excellencies that makes him a great and understanding citizen as well, and, unresponsive to the things that life holds of beauty and of other worth. The presence of men eminent in all the various departments of knowledge imparts dignity, worth and stability to the whole institution. All the professors in such an intellectual empire are under a compulsion which tends constantly to keep them at a higher level. Their products come to bear the impacts of a greater universality of interests and character. The spirit of emulation with other faculties of high scholarship improves the standard of work and makes for a better product. The center for continuation study—the brain child of the late lamented President Coffman—is one of the finest projects in modern education. Its work is being watched throughout the world. The medical continuation project is most ably directed by Dr.

Wm. O'Brien. He knows what the profession needs most, and through this agency he is giving a matchless service to it. I saw him resurrect a man sixty years old who died professionally thirty years ago.

President Ford, we of the alumni have faith in your intellectual and administrative leadership. We know you are steeped in the university tradition. Great historian that you are, you are capable of mentally encompassing not only the past but also capable of envisioning the fateful future of a world beset with trouble. As an alumnus and as a citizen of this state, I took occasion but a year ago to express gratification over your election to succeed America's greatest educational statesman, Dr. Coffman, to the presidency of the university and to congratulate the commonwealth on so wise a choice. In that same message I wrote: "It has been the greater part of your distinguished life-work here to help build and fashion the institution into the great intangible thing it has become, now ranked among the foremost universities in the nation. You have in your twenty-five years of association with it watched it grow in attendance from 5,000 to 15,000 students—the second largest state university in America. You have seen the campus extended and the buildings multiply. You have observed its faculty increase from a few hundred to nearly 1,500, numbered among which are some of the world's great scholars. You have seen not only departments added but also deepened until one can in truth say of the university tonight that there is no appreciable province in the dominion of the mind to which it is alien."

Lying deep in this intellectual firmament and gleaming like a flaming Orion, shines the medical school—now celebrating the 50th anniversary of its emergence into the galaxy of departments. You will, I know, guard its interests that it may grow into a stature exceeded by no other medical school in the world. I know I am expressing tonight the sincere sentiments of the medical alumni who once were inhabitants on this star, when I pledge you our continued loyalty, coöperation and interest.

To reminisce, I must confess that compared with the modern graduate in medicine, those of us who went from out of the department in what has come to be termed the "horse and buggy" days did not know much. But let me tonight say that those boys were the matchless spirits

who in their day did such kindly and faithful service under the most trying circumstances as to gain for the profession the well earned title, "The friend of man." Many of them lie tonight in the little cemeteries by the trails they travelled through blinding winter storms, no lights to guide them—only the inner light and the irrepressible spirit that drove the country doctor to do his job—when no other human being dared the night. Their meager medical training and their little medical kits may have seemed but small bastions against the adverse catastrophes they faced in those early days, but history will record to their everlasting honor that nowhere in life's trying situations have they been quite so large. They were an earnest and an answered prayer—and a fortress to countless homes and distant hamlets on frontier settlements where most of the boys went to administer.

"From the voiceless lips of those unreplying dead," I tonight bring greetings and words of gratitude to the medical school which was to them the source of the inspiration and the medical training that gave the faith and the competence they had to carry on. These heroes had little of the comforts in which the modern graduates wallow. They had no high-powered, palatial, enclosed, warm automobiles—only open buggies and sleighs—the sleet, the rains, and the pitiless blinding snows driving in upon them as they drove over trackless prairies. They had little practical laboratory knowledge, no hospitals near, no x-ray machines as we now enjoy. The days' and nights' experiences of those days, marooned and alone, haunt me like a nightmare to this day.

These early graduates were plain men, quite imperfect in training and equipment, but they answered the calls on wide fronts to face every form of disease and emergency—and because of the storms, often at the peril of their lives. They were plentifully bewildered, plentifully mired in medical ignorance as we know medicine today, but they did their job, their job went on in outer peace. They closed an epoch in the progress of medicine, not so impressive as now, but they need not be ashamed of the colors that they flew. They sleep tonight among our sacred dead. They upheld the best traditions of an honorable Guild.

Among those noble dead who lived those early days with high emprise, I am impelled to make special mention of one because of what he was and of what he wrought for his generation. I

have reference to Dr. Herman Johnson, member of the class of 1901, who died five years ago at Dawson, Minnesota—the scene of his earthly labors. I have not the time to etch him as I would like—only time to give you glimpses of this lordly man—beloved by every member of the medical profession of Minnesota and the entire Northwest, admired and respected by everyone who knew him. If the hierarchy of medicine ever elevated a man to sainthood, something which a few really deserve, the profession would by acclamation vote him the citation. Personally I would crave the honor of casting the first white ballot. His physique, his features, his leonine mane, his eyes when in conflict, his heart tender as a woman's when unperturbed, his loyalty to friend, his uncanny power of analyzing complex situations, his withering oratory when on fire, his hatred of sham and hypocrisy—these characteristics stand out in the memory of him.

He was a pioneer physician but his life-span bridged two epochs. He embodied in spirit and in practice all the virtues of humanity, charity, honesty, personal integrity, humility. He was a physician and a surgeon steeped in fidelity to the tenets of his Guild. He was fearless, capable, dynamic. In the early days out there on the western front, he drove out into the dark nights to minister, often to operate emergencies on kitchen tables with only candles and kerosene lamps to light him. His percentage of recoveries measured quite well up to that of the surgeon surrounded by all the accessories of the modern operating room.

He was to his community a wise counselor, to the sick "a pillar of fire by night," and by day, "the shadow of a great rock in a weary land."

His faith in individual medicine was to him an obsession to the last. Great student of human nature that he was, he realized that the regimentation of the noble Guild would eventually rob the individual member of his initiative, blast the soul out of the profession, tend to degrade it to a vulgar trade union, make the doctor a hireling

of the state and dominated by the mediocrity of a political pressure group. In his heart he prayed that the high profession of medicine would be saved from such degradation. And I know that I am voicing the sentiments of the alumni when I say "Amen" to his prayer. You will pardon the digression when I say that some day it may come to pass that you all may lose even your most cherished liberties that patriots through the centuries fought and died for. When there are enough alien-minded mongrels among us who cease to appreciate free speech, the free ballot, a free press, free enterprise and freedom to worship as the individual conscience dictates, we will soon lose the freedom that we have known and our fate will fall into the hands of merciless dictatorships with their bureaucratic rule. Then preachers will be told what to preach; teachers will be told what to teach; women praying to their God for themselves and their children will be destroyed—for the dictator will have no other God before him.

So devotedly and endlessly did this man fight for his profession against politics, charlatanism and quackery that the struggle so undermined his health that he died earlier than his time, a martyr to the cause of scientific medicine here and everywhere. He led the fight in the legislature of Minnesota to place upon the statute books the so-called Basic Science law—which has since become a model for a score of other states in the Union.

In closing, I wish to address him tonight "where beyond these voices there is peace" in the lines of Wordsworth:

Herman:

"Thou hast left behind
Powers that will work for thee.
There's not a breathing of the common wind
That will forget thee;
Thou hast great allies;
Thy friends are exultations,
Agonies
And love, and man's unconquerable mind."

VERTIGO*

W. T. WENNER, M.D.

St. Cloud, Minnesota

VERTIGO is a subjective sensation of disturbed equilibrium often accompanied by a slight clouding of consciousness. It may be manifested in the form of (1) giddiness, which is a mild degree of fainting with a momentary loss of one's balance; (2) a sense of rotation, either with objects rotating about an individual or an individual rotating about objects; and (3) a feeling of pulsion manifested as a veering of the individual to one side or the other. All of the above sensations appear in the form of attacks. They are not continuous or constant.

It is well to remember that patients frequently do not distinguish true vertigo from nausea and fainting, because vertigo may be associated with both.

Equilibrium in the human body is maintained by: (1) afferent impulses to the brain; (2) efferent impulses through the motor tracts and to the muscles; or (3) coördinating centers in various parts of the brain.

Afferent impulses come from: (1) superficial and deep sensibilities located in the skin, muscle tendons and joints; (2) visual impressions; and (3) the vestibular portion of the internal ear.

It is the vestibular portion of the internal ear or labyrinth that is the most important factor in maintaining equilibrium. All factors are not imperative to maintain equilibrium, but at least two are necessary for the purpose. When one factor is interfered with, the others compensate and carry on the function. For example, a blind man can maintain balance with aid of his labyrinth, muscle and joint sense; a tabetic will maintain his equilibrium through his vestibule and visual function; and a deaf mute, having no vestibular function, maintains his equilibrium with his remaining functions. Sudden loss of labyrinthine function by disease will cause very unpleasant vertigo for a while, but compensation takes place and the individual adjusts to it.

Any deviation caused by irritation or destruction of any of the normal factors concerned in maintaining equilibrium results in vertigo.

Etiologic Factors of Vertigo

First are those caused by general systemic conditions such as cardiac, renal, or arteriosclerotic pathology, pernicious anemia, leukemia, operating through disturbances of the labyrinthine circulation. Drugs like quinine, salicylates, alcohol and tobacco may be responsible. Infection due to teeth, tonsils or sinuses may be the offending agent. Gastro-intestinal disorders of which the gallbladder has the highest incidence may cause vertigo. Trousseau⁵ reports a series of cases of vertigo which he terms "gastrogenic vertigo," the earmarks of which are a direct relation to digestion proper and therapeutic response to dietetic and medical treatment. Analyzing his case reports, one is left with the opinion that many of his patients are the sufferers from gallbladder disease, which gives emphasis to this as a cause of vertigo.

In addition to the first group of causative agents such as general systemic factors are ocular conditions, diseases of the ear, and finally, diseases of the brain.

The following brief case report illustrates the gallbladder as a cause of vertigo:

A. H., male, aged thirty-six, a grocer, complained of low-grade temperature of three months' duration, gastric distress, frontal headaches extending to the occiput, attacks of vertigo associated at times with vomiting, weakness, and incapacitation for work. He was referred for refraction and checkup on sinuses.

The fundi showed tortuosity of vessels in both eyes. Error in refraction was negligible. The peripheral fields were normal. There was no nasal congestion and the sinuses were clear. Ears were normal. In the vestibular caloric tests the reaction time was well within normal limits: 40 seconds in the right and 45 seconds in the left. With these normal findings it was felt that ears, sinuses and eyes were not a factor, that there was no pathology in the cerebro-pontile angles, and that there was some general cause for the vertigo. The patient had a cholecystectomy done several weeks later with complete relief of all symptoms.

Ocular conditions causing vertigo are chiefly due to muscular imbalance, which increases when the gaze is in the direction of the paretic muscle. Occluding one eye will always relieve the vertigo. Poorly adjusted glasses, especially if the correc-

*Read at the Northern Minnesota Medical Association, Detroit Lakes, September 8, 1939.

tion contains a high cylinder or if the cylinder is at an improper axis, may result in vertigo. A person wearing bifocals for the first time may have a temporary vertigo until adjustment is made.

Aural Conditions Causing Vertigo

Pathologic conditions of the external auditory canal, such as foreign bodies or external otitis, may result in vertigo by increasing pressure or irritation of the ear drum. Middle ear catarrhal otitis media and blocking of the eustachian tube may also be a cause. Suppuration of the middle ear, acute or chronic, may cause vertigo by infection of the labyrinth. A sudden onset of vertigo, with nausea, vomiting and nystagmus, accompanied by a unilateral deafness without the presence of suppuration, has been described by Meniere as due to a hemorrhage into the labyrinth.

Brain Conditions Causing Vertigo

Intracranial lesions, such as tumors of the frontoparietal lobes, as well as those of the cerebellum, may cause vertigo. Weisenberg in his study concluded that vertigo in cases of brain tumor is caused by an increase in intracranial pressure, and that tumors of the posterior fossa are more likely to cause vertigo. He found no characteristic type of vertigo in any type of tumor and also found that tumors may exist without vertigo.

Trauma to the head may be followed by vertigo for an indefinite period due to cerebral concussion. This is important in industrial and civil cases. Vestibular tests may give some information as to malingering in such cases.

In certain brain conditions, such as multiple sclerosis and encephalitis, vertigo is a symptom in certain stages of the disease.

Diagnosis of the Etiology of Vertigo

Diagnosis of the cause of vertigo should be made only after a careful history and a complete physical examination to rule out any of the aforementioned systemic conditions, neurologic or cerebral diseases, and also aural pathology. An important measure in the diagnosis is the performance of the vestibular tests. This is a relatively simple procedure and can be performed by anyone. Even the interpretations are not difficult. The information received, whether negative or positive, is an invaluable aid. The rotation test requires a special chair, but the caloric

test requires only water, so it will be described in detail.

The importance of the caloric test is seen in the following case:

Mr. W., aged thirty-three, first presented himself in 1929 with the history of impaired hearing of the left ear of several months' duration. The Weber test was referred to the left ear. Bone conduction of the left ear was increased as compared with air conduction. He was not seen again until 1936, when he was referred for fundus examination. He then gave the history that for six months he had had attacks of vertigo and stumbled over objects. He had an old comitant convergence of the right eye. Visual tests demonstrated 20/50 vision on the right and 20/25 vision on the left side. Fundus examination showed a slight blurring of the upper and nasal disc margin of the left eye. He was referred to a competent neurologist, who found nystagmus to left, slight slurring speech, slight ataxia of left arm and leg, increased knee jerks grade +1 on left, and some impairment of deep pain sense both ankles. On these findings a diagnosis of multiple sclerosis was made and intravenous typhoid therapy instituted. He was seen by another neurologist several months later, at which time there was some improvement in his speech. His ataxia and loss of balance showed no change. Neurological findings were the same.

The patient was not seen again until February, 1937, at which time there was edema of the left disc and definite blurring of the right disc. Hearing of the left ear had markedly diminished. He was seen next in October, 1937, suffering from intense headaches. Examination then revealed total deafness of the left ear, left labyrinth functionless, marked reduction in vision, and bilateral choked discs. The spinal fluid was under markedly increased pressure. Operation demonstrated an acoustic neuroma of the left eighth nerve. The patient died twenty-four hours after operation.

Reviewing this unfortunate history, one is impressed with certain features. In the first place there was a long duration of symptoms, a period of nearly nine years. Undoubtedly the first symptom, impaired hearing, heralded the beginning of the acoustic neuroma. Further, failure to perform vestibular tests was responsible for the lack of information which would have made an earlier, correct diagnosis possible.

Two Methods of Caloric Test

1. *Koprak or Minimal Method.*—Use a 10 c.c. syringe and water at 55° F. Inject against the upper posterior part of the drum. Nystagmus appears in 15 to 25 seconds and lasts 60 to 100 seconds. The labyrinth is hyperactive when nys-

tagmus appears in 15 seconds or continues longer than 100 seconds.

2. *Mass douching* is probably more time consuming, but it is more satisfactory to study the vertigo and past-pointing. The technic is as follows:

- | | |
|--|--|
| 1. Douche the right ear with water at 68° F. and head 30° forward. | 1. Requires about 40 seconds of douching. Nystagmus will be to the left. Past-pointing will be about 8 inches to right with each hand. Sensation of turning to the left—tendency to fall to the right. |
| 2. After nystagmus and past-pointing have been quickly noted, bend head back 60° and note reactions. | 2. Same as above except nystagmus is horizontal. |
| 3. Repeat 1 and 2 in left ear. | 3. Same as in 1 and 2 but in opposite directions. |

The caloric method tests each ear separately, as well as the vertical and horizontal canals separately. With the head forward 30°, the vertical canals, and with the head backward 60°, the horizontal canals are tested. Sometimes during the course of these tests, varying with each patient, there is a certain amount of pallor, nausea and perspiration, which is a normal reaction of the sympathetic nervous system.

If all of the responses are present, either normally or more or less proportionately exaggerated or diminished, it means that both inner ears are intact, that there probably is not present any lesion in either of the cerebello-pontile angles, and that if any vertigo exists it is probably due to some general cause.⁴

Treatment of Vertigo

The literature on treatment of vertigo is both voluminous and varied, signifying that there is nothing specific for the malady. The treatment, of course, is directed toward the cause and its elimination when possible.

Brain tumors are neuro-surgical problems. Aural conditions, especially suppurative, are in most instances relieved by radical mastoidectomy. An aural condition frequently causing vertigo is a catarrh of the eustachian tube, the result of an

acute head cold, nasal obstruction, sinus infection, improper blowing of the nose, or exposure to a draught. Therefore, the first step in treating this condition is to procure the patency of the eustachian tubes, and the next step is to maintain it.

Atkinson,¹ in his study, states that "a large proportion of all cases of vertigo are due simply and solely to a unilateral eustachian obstruction, the cure of which will cure the dizziness. Eustachian catheterization is the sheet anchor, and not until it has been tried and failed or been proven not to be the cause of the symptom, should it be abandoned. As long as it improved, even if only temporarily, it should be continued."

Patients have been relieved of vertigo by removal of abscessed teeth or infected tonsils or cleaning up of a sinus infection. Gastro-intestinal disturbances and dietetic irregularities should be corrected. Circulatory conditions must be given proper attention. In a large number of cases, the cause is obscure and the attention should be directed to treatment of the attack, first principle of which is immobility, as the patient soon learns that the slightest movement provokes or aggravates vertigo. A quiet dark room more conducive to rest should be used. It is well to promote elimination by giving a mild cathartic. Sedatives should be given. The patient is usually vomiting, so sedatives are not tolerated orally. Three grains of sodium luminal subcutaneously or sodium amytal rectally are usually effective.

The treatment of Meniere's disease is directed not to the cause, as that is unknown, but to removing or reducing the liability to the attacks. Fatigue, worry, insomnia are factors aggravating or precipitating an attack of vertigo. The psychological aspect of the case, therefore, is important. These patients are usually of anxious temperament and need continued encouragement and regulation of their mode of living, such as adequate relaxation and avoidance of alcohol and tobacco.

The medical treatment recommended by Furstenberg³ and his co-workers opens a new approach to this problem, and should be instituted in all cases when one fails to discover and eliminate probable causes. It is based on the theory that the vertigo is due to a water-logged condition of the static labyrinth. The edema is not water alone, but a solution of electrolytes, chiefly sodium salts and water.

The therapeutic indications are: (1) to permit as small an intake of sodium as possible; and (2) to prevent the accumulation of sodium by the body. The first is easily attained by means of diet, and the second by the administration of acid producing salts, such as ammonium chloride. When these two factors have been controlled, the intake of water does not need to be considered, although excessive quantities of liquids should be avoided.

In the series reported by these authors, the following treatment was followed:

1. Proteins were unrestricted.
2. Calories were permitted as indicated.
3. A low salt diet was advised.
4. Ammonium chloride was given at the rate of 3.0 Gms. with each meal (6 capsules, each containing $7\frac{1}{2}$ grains, are taken during the meal) for three days and omitted for two days. The capsules should not be replaced by the chocolate-coated or the enteric-coated pills, because they sometimes pass through the gastro-intestinal tract without being absorbed. The ammonium chloride can be given in this dosage for an indefinite time without injurious effects.

In not one instance did the writers fail to

produce an attack by the administration of sodium, and not once were they disappointed in obtaining complete relief by the medical therapy above described.

When all attempts with medical therapy have failed, surgical procedure may be necessary to give some of these unfortunate people relief. Dandy² recommends surgical severance of the vestibular portion of the eighth nerve. Other surgical procedures recommended are destruction of the labyrinth with absolute alcohol.

Summary

1. Vertigo is defined.
2. Importance of vestibular testing is stressed.
3. Two cases are reported.
4. Furstenberg method of medical treatment is advocated.

SYMPATHETIC NEUROBLASTOMA*

Report of Case

O. B. FESENMAIER, M.D.
New Ulm, Minnesota

SYMPATHETIC neuroblastoma of the left suprarenal gland was first described by Hutchinson in 1907.² Since then a few more cases have been reported and additional studies have been made regarding this condition. Neuroblastomas are neurogenic in origin and are found in the adrenal medulla or in the sympathetic ganglions along the spine. Neuroblastomas are also known as neurocytomas or sympathoblastomas. The metastases, which always occur early, appear in the retroperitoneal glands, the orbits and the long bones. The metastatic masses, which are firmly attached to the bone as in this case, contain many bony spicules. The primary tumor, which invariably involves the left adrenal gland, varies in size and is usually palpable through the

abdomen. In this case, the tumor was not palpable.

Microscopically, one sees a large number of round cells with hyperchromatic nuclei, fibrils arranged in longitudinal bundles or compact round balls, and imperfect ganglion cells. The round cells are arranged around these fibrils to form rosettes. The formation of rosettes by the round cells is a characteristic microscopic finding.

Most often neuroblastomas are seen in young male children, especially those under the age of four.

In sympathetic neuroblastoma, the patient usually complains of pain in the extremities, the back, or in the neck. The pain may be of a dull aching type or it may simulate pain found in rheumatic fever. The pain may be referred only

*Read before the Southern Minnesota Medical Association, New Ulm, Minnesota, September 18, 1939.

to the thigh, leg, and spine or it may be general throughout the body. Movement of any involved part increases the pain. At times, an abnormal gait may be the first symptom. Attacks like this may last for a few weeks, subside for a while, only to recur again.

In some cases, pain in the abdomen leading to the discovery of a palpable mass⁴ will be the initial finding. Often swelling of the eyelids, or protrusion of the eyes may attract the attention of the parents. The face may also become involved due to metastases. Frequently, the eyelids are swollen and discolored. Protrusion of one or both eyeballs occurs and may be so marked as to cause necrosis. A gradual loss of eyesight is a common complaint. Leinfelder³ states that the ocular signs are caused by increased intracranial pressure and metastases to the orbit. Often nodular swellings are palpable on the skull. Swallowing or other movements of the jaw causes pain in some cases. Frequently a marked facial palsy is present. The patient may also complain of ringing in the ears and a gradual loss of hearing.

The glands, especially in the inguinal and the submaxillary region, are often enlarged and painful. This may be an early or late manifestation. Other clinical findings are a loss of weight and appetite, vomiting, marked emaciation and weakness, irritability, nervousness, fever, sweats, tachycardia, dyspnea, and incontinence of the bladder and bowel.

In early cases, x-ray examination of the bones usually reveals no pathological changes. In this case, no changes were noticed when the patient was seen by another physician. Later on, x-ray examination of the skeleton reveals interesting findings. Marked areas of intensive bone infiltration appear in the pelvis, femur, skull, and spine. The bones show a granular type of osteoporosis due to minute foci of resorption. The x-ray picture reveals an intensive and diffuse process of new bone formation and also destruction of bone. Doub¹ states that in many instances the resorption is of uneven density, suggesting a diffuse infiltration rather than a massive destruction. A striking reaction of the periosteum is its elevation with a diffuse infiltration of osseous tissue and the formation of fine spicules.

The blood picture shows a pronounced secondary anemia, a non-progressive erythrocytic re-

generative shift and considerable myeloid immaturity. The presence of myeloid cells makes it difficult at times to differentiate between the leukemias and neuroblastoma.

Neuroblastoma is a very mystifying disease to diagnose. It must be differentiated from the leukemias, especially the aleukemic leukemia, chloroma, Ewing's sarcoma, myeloma, hyperparathyroid disease, rheumatic fever, tuberculosis, and hypernephroma. Neuroblastoma must always be considered in young male children when pain in the bones, bulging of the eyeball, and abdominal mass are present.

The prognosis is hopeless. There is a rapid and downward progress which is only interrupted by some abatement of symptoms for a few weeks, followed by relapses and finally death within a couple of months. No treatment is effective. Radiation treatment offers only mild amelioration and at times prevents necrosis of the eyeball.

Case Report

The patient, a white boy of fourteen, was seen by me on February 7, 1937, complaining of rheumatic-like pain in the left shoulder, elbow, hip, and in the back. The patient first noticed the pain in the hip during the summer of 1936. The pain would last for a few weeks, then remain quiescent for a while and then was succeeded by a similar recurrence. The number of attacks gradually increased during the fall of 1936, preventing him from going to school. He began to limp and later needed assistance in walking. During the last three weeks he was bedridden.

Physical examination revealed a pale, undernourished and acutely ill boy. The pulse was regular, the rate was 130, and the temperature was 100. Both eyelids were slightly swollen but the eyeballs showed no protrusion. Examination of the chest revealed nothing of importance except a strong apical impulse. Abdominal examination was essentially negative. The extremities showed a slight wasting and the right leg was slightly spastic. Movement of the arm, legs, or back caused severe pain.

The urine was essentially negative. Blood count showed 3,000,000 red cells, 9,000 white cells, 42 per cent hemoglobin, and 0.6 color index. Blood smear examination revealed some anisocytosis and poikilocytosis, 3 juveniles, 44 stab cells, 24 segmented cells, 26 lymphocytes, and 3 monocytes. Later on some myelocytes appeared. The blood Wassermann reaction and Mantoux skin tests were negative. The blood sedimentation rate was greatly increased.

My first impression was rheumatic fever, but as the case mysteriously progressed with new symptoms and signs, rheumatic fever was ruled out.

The pain on the left side gradually subsided while the right hip and leg increased in severity during the next few weeks. It was noted also that the right leg was now flexed and externally rotated and the head of the right femur appeared to be displaced backward. These clinical findings suggested a posterior dislocation of the femur resulting from some undetermined bone pathology. The patient was able to enter the hospital on February 17, 1937, for further clinical investigation.

X-ray examination of the hip showed a posterior

dislocation of the right hip with formation of a new socket on the outer aspect of the ilium. The pelvis, femora, and the skull showed a granular type of osteoporosis and a diffused process of new bone formation. The periosteum was elevated, especially in the femora. Marked bony infiltration was also seen on the lower

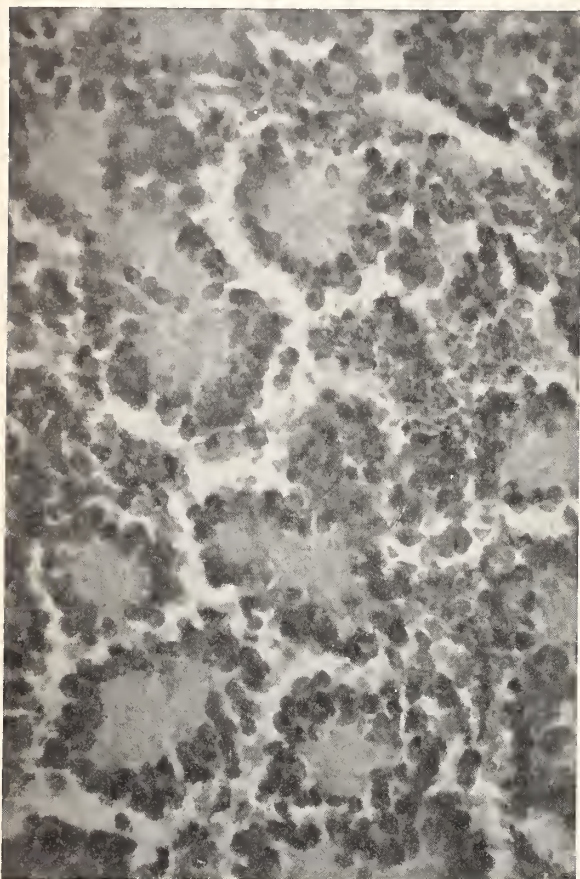

Fig. 1. Microscopic section of neuroblastoma involving left adrenal gland showing typical rosettes formed by round cells.

end of the left femur. A urogram showed no abnormal findings.

The course during the succeeding weeks was downward. Both eyelids began to swell and gradually the eyeballs became more protruded. There was pain upon swallowing and ringing in the ears. Some abdominal

pain was present but no mass was palpable. At this time, my impression was that of neuroblastoma of the left adrenal gland but hyperparathyroid disease had to be ruled out. The blood calcium was normal. However, such a finding frequently occurs in hyperparathyroid disease. To a certain extent the clinical manifestations definitely pointed towards neuroblastoma. But if an incorrect diagnosis of neuroblastoma had been made when really a hyperfunctioning parathyroid gland was the causative factor, it would have been regretful indeed, since removal of the enlarged parathyroid gland would give a good result.

A decision was made to explore the parathyroid gland, since there was nothing to lose and everything to gain by such an operation. The operation was performed by Dr. Dubbe and myself but no pathology was found. With this disheartening knowledge a definite clinical diagnosis of neuroblastoma was made and no hope for a cure was given to the parents. The patient was later seen at an outside clinic where a diagnosis of multiple central nervous system metastases possibly due to a hydronephroma was made.

During the summer of 1937, there was a progressive downward course. The eyes became more protruded than ever and blindness was nearly absolute. Diffused enlargements appeared on the frontal area of the skull. The coronal sutures were somewhat separated. The lower jaw was also studded with small round masses. The bowels and bladder were incontinent and the crest of the left ilium was enlarged. The patient gradually became weaker and he died on November 23, 1937. The illness lasted a year and four months.

Postmortem examination of the abdomen revealed rounded and flattened masses attached to the inner aspect of the left and right ilium. The mass on the left side was removed with difficulty and measured 6 cm. in length, 4 cm. in width, and 3 cm. in thickness. The mass was well encapsulated except for the portion which was attached to the ilium. Many bony spicules which were attached to the ilium projected into the tumor. The mass, which was smaller on the right side, was not removed. The lymph nodes along both sides of the spine were enlarged and bright red in color. The adrenal glands were normal in size. Sectioning of the left gland revealed a small irregular but well localized dark area about 1 cm. in diameter. The right gland showed no apparent pathology. Histological examination of the left adrenal gland and of a lymph node showed the typical rosette formation composed of small round cells (Fig. 1) which is found in neuroblastoma.

DIAGNOSTIC METHODS IN UNDULANT FEVER (BRUCELLOSIS) WITH RESULTS OF A SURVEY OF 8,124 PERSONS

S. E. GOULD, Eloise, Mich., and I. F. HUDDLESON, East Lansing, Mich. (*Journal A. M. A.*, Dec. 11, 1937), describe briefly the performance and interpretation of the laboratory methods which at present are believed to be most useful in the diagnosis of undulant fever (brucellosis) and report some of the results of a survey of the incidence of brucellosis in a large county hospital. An unusual opportunity to study the incidence of *Brucella* infection presented itself at Eloise Hospital and Infirmary, whose milk supply was partly infected with *Brucella*. All persons in the institution were first tested intradermally with brucellergin. Among 8,124 persons tested, 845, or 10.3 per cent, showed positive brucellergin reactions. The incidence roughly paralleled the average length of stay in the various groups in the institution. The incidence was lowest among the hospitalized group (6.2 per cent), whose average stay was the shortest, and greatest among the mental patients (15.4 per cent), whose average stay was the longest. The brucellergin test was found to be the most sensitive test in the diagnosis of brucellosis. If the test is negative, brucellosis will usually be ruled out. If the test is positive, the opsonic test should then be performed to determine whether infection or immunity is present. A negative agglutination test does not rule out *Brucella* infection. The agglutination test is diagnostic only in a small percentage of cases and gives no information as to the immune status of the subject. Carriers of *Brucella* may be of some importance in the spread of the disease.

CASE REPORTS

PNEUMOCOCCUS (TYPE III) MENINGITIS WITH RECOVERY

L. R. CRITCHFIELD, M.D., L. T. SIMONS, M.D., T. H. EMMENS, M.D.,
and F. W. NEWELL, M.D.

Saint Paul, Minnesota

The mortality of pneumococcus meningitis is difficult to compute because of the lack of a large number of figures concerning its incidence. However, most authorities consider it almost universally fatal.² Tripoli¹⁴ reports 468 cases of purulent meningitis occurring in a ten-year period at the Louisiana State Charity Hospital with 111 (24 per cent) being due to the pneumococcus with but one recovery and that in the case of an untyped organism. At Boston Children's Hospital 74 (26 per cent) of a series of 284 meningitides were due to the pneumococcus with one recovery, that being a type XII organism.³ This high incidence has not been noted at Ancker Hospital, where in the past nine years only 5.5 per cent of the cases of meningitis were caused by the pneumococcus with only one recovery here reported. Neal⁴ found only sixty-six cases of meningitis due to this organism in 1,259 cases, and then (1920) considered the disease universally fatal. Shaffer,¹¹ in 1938, considered the disease as carrying a mortality of at least 98 per cent.

There are, however, numerous reports of recoveries from this infection in the literature. One hundred and eighty-five cures of all types of pneumococcus meningitis were reported prior to 1937 and in that year seven additional were reported.¹³ With the widespread use of sulfanilamide and related drugs since then, there have been increasing numbers of recoveries reported.

No special type of pneumococcus predominates as a cause of meningitis but the frequent occurrence of the Type III organism secondary to disease of the middle ear or paranasal sinuses is well known. Neal⁹ found it in thirty-five out of seventy-five cases of pneumococcus meningitis of otogenic or paranasal sinus origin. The organism was the cause of meningitis in only twelve cases of meningitis in a series of 139 caused by infections other than those mentioned. Neuman¹⁰ analyzing 101 cases of otogenic meningitis found the pneumococcus Type III organism to be the offender in seventy-two cases and other types the cause in sixteen.

In spite of this evidently large incidence of Type III pneumococcus meningitis, there have been very few recoveries noted in the literature, although this number is enlarging rapidly with the use of sulfanilamide and related compounds. Allmen¹ in 1937 found but four previous cures of the infections and to this added one of his own which was treated with subarachnoid drainage and radical mastoidectomy. Two of the patients received antipneumococcus serum alone, one ethyl hydrocupreine, and other case potassium permanganate enemas only. Gubner⁵ and Garfin³ reported re-

coveries following radical mastoid surgery and sulfanilamide therapy. Magruder⁸ had a recovery with sulfanilamide, myringectomy and subarachnoid drainage, as did Silverman.¹² Silverman's patient died after four months with a clinical meningeal reaction but no organisms in the spinal fluid. MacKeith⁷ had a recovery following remission when the drug was discontinued using M and B 693 (sulfapyridine) and this was apparently the first recovery from a Type III organism in which this drug was used.

In October, 1939, Hodes, Gimbel and Burnett⁶ reported seventeen cases of pneumococcus meningitis, with eight recoveries. They used sulfapyridine and also sodium sulfapyridine. Two of these cases of Type III pneumococcus meningitis were isolated.

Case Report

L. R., an eighteen-year-old young woman, white, was admitted to Ancker Hospital, Saint Paul, on November 21, 1939. She was very lethargic and semi-rational, being aroused only by loud and persistent questioning. She complained of severe headaches, and stiff neck and back. The history obtained from relatives revealed that seven days prior to admission she had developed a cold, followed five days later by pain in the right ear and generalized headache. Headache became steadily worse and purulent discharge from the right ear was noticed on November 19. The symptoms became progressively worse. On the day before admission she screamed several times and had emesis. No convulsions or paralysis were evident.

Past history revealed that the patient had had frequent colds and in 1938 had had acute purulent bilateral otitis media.

On admission the patient was very listless and did not respond well to questioning. She was well nourished. Her face was flushed and she appeared to be acutely ill. Temperature was 102.8, pulse 125, respiration 16, blood pressure 130/70. There was a purulent discharge in the right external auditory canal. Fundoscopic examination showed a slight papilledema of both discs. She was in opisthotonos with marked rigidity of neck and back. Kernig and Brudzinski signs were positive. The tendon reflexes were all positive. The spinal fluid was under increased pressure and heavy ground glass in appearance.

Admission Diagnosis: Acute suppurative otitis media (R); purulent meningitis.

November 21, 1939, 7:30 a. m.—Spinal fluid 15 c.c. pressure III, ground glass appearance. Leukocytes 7,800 (P.M.N. 86 per cent). No organisms found in direct smear. T. 102. P. 100.0, R. 16.

Smears made from purulent discharge from right ear were investigated thoroughly in an attempt to determine the bacterial cause of the meningitis. Many Gram-positive cocci were found but further differentiation was not possible during the first 24-hours. On the basis of clinical possibility sulfanilamide was or-

CASE REPORTS

dered and also 20 c.c. of polyvalent antistreptococcus serum was administered (intramuscularly). Headache controlled by codeine sulfate.

12:00 noon—T. 105.2. P. 128.

3:00 P.M.—25 c.c. spinal fluid removed.

10:00 P.M.—25 c.c. spinal fluid of ground glass appearance. Pressure 425 mm. Headache improved.

Blood examination: Hemoglobin 65 per cent—R.B.C. 3,340,000; W.B.C. 28,300; P.M.N. 92 per cent; Lymph. 8 per cent.

Urinalysis: amber; acid; sp. gr. 1.030; heavy traces of albumin.

Transfusion 200 c.c. of blood and 500 c.c. of normal salt solution were administered intravenously.

November 22, 1939.—T. 103.6. Severe headache. Some cough. Chest finding negative. Spinal fluid, 25 c.c. Pressure, 300 m.m., 2,670 leukocytes.

Laboratory Report: Type III pneumococcus found in cultures of first spinal fluid obtained.

Therapy changed. Sulfanilamide discontinued. Sulfapyridine administered, two doses of grains XXX each at four-hour intervals and then grains XV q.4.h. accompanied with equal amounts of sodium bicarbonate.

Transfusion—250 c.c. blood, 400 c.c. n.s.sol.—intravenously.

7:15 p. m.—80 c.c. of 5 per cent sodium sulfapyridine solution (60 grains) administered intravenously. Patient had emesis following this injection and emesis continued at intervals for thirty-six hours.

9:15 p. m.—Spinal fluid 30 c.c. slightly cloudy. 3,600 leukocytes (P.M.N. 83 per cent).

A consultant otologist recommended paracentesis of the right ear drum to increase drainage. This was performed. The question of immediate surgery of the right mastoid bone was considered. Although there was some tenderness over the mastoid body, conservative management was decided upon.

November 23, 1939—12:01 a. m.—T. 100.

40 c.c. 5 per cent sodium sulfapyridine (30 grains) administered intravenously. Emesis.

7:00 a. m.—40 c.c. 5 per cent sodium sulfapyridine (30 grains) intravenously. Free sulfapyridine 17.3 mgm. per 100 c.c. of blood.

3:00 a. m.—Spinal fluid 15 c.c. Leukocytes, 572.

Therapy: Sulfapyridine gr. XV, given per os q.4.h. x 6.

November 24, 1939, 1:00 p. m.—T. 102. Spinal fluid 15 c.c. almost clear. Leukocytes, 218.

Transfusion, 250 c.c. blood, 500 c.c. n.s.sol.—intravenously.

Sulfapyridine blood concentration, 10 mgm. per 100 c.c.

November 25, 1939.—T. 102. Definite improvement. Spinal fluid, 15 c.c. Leukocytes, 138. Sulfapyridine blood concentration, 8.0 mgm.

November 26, 1939.—T. 101. Some headache. Sulfapyridine blood concentration, 7.3 mgm.

November 27, 1939.—T. 102.2 Increase of headache. Spinal fluid 25 c.c. almost clear. Leukocytes, 50.

40 c.c. 5 per cent sodium sulfapyridine (30 grains) intravenously.

Transfusion—250 c.c. blood, 500 c.c. n.c.sol. + 5 per cent glucose.

Sulfapyridine blood concentration, 9.3 mgms.

Sulfapyridine spinal fluid concentration, 5.0 mgms.

November 28, 1939.—T. 101. More responsive, clear mentally.

Transfusion—blood 250 c.c., 5 per cent glucose in n.s.sol. 500 c.c.

Sulfapyridine blood concentration, 7.3 mgms.

Betaxin, 1 c.c. subcutaneously b.i.d.

Lextron, 2 caps. t.i.d.

Urine, albumin ++.

November 29, 1939.—T. 100.8. Spinal fluid 15 c.c.; clear; 35 leukocytes. Urine, albumen + (thereafter

urine was normal on all examinations. No red blood cells reported at any time).

December 1, 1939.—Mentally clear. Very little stiffness of neck.

Sulfapyridine blood concentration 8.3.

Sulfapyridine dosage reduced to grains X q.4.h. x 6 Hemoglobin 59 per cent. White blood count, 13,050.

December 14, 1939.—Spinal fluid 20 c.c., clear. Seventeen leukocytes.

Cultures of spinal fluid show no growth.

Sulfapyridine spinal fluid concentration, 3.4 mgm.

Sulfapyridine blood concentration, 5.4 mgm.

Blood sugar, 156 mgm. per 100 c.c.

Spinal fluid sugar, 52 mgm. per 100 c.c.

Blood calcium, 13 mgm. per 100 c.c.

P. S. P. test—61 per cent in two hours.

Dosage of sulfapyridine was gradually reduced to gr. X b.i.d.

Patient was discharged from the hospital on December 24, 1939, at which time she was free from evidence of disease. On January 8, 1940, she continued to remain well and was permitted to return to her home out of town.

In a discussion of this case the following considerations are worthy of mention:

1. Early diagnosis of the bacterial agent causing purulent meningitis. At the time of the *first spinal drainage* steps should be taken toward diagnosis of the causative organism. This calls for active coöperation and skill on the part of medical and laboratory staff.

2. Recovery in this case, in all probability, depended upon the early and sufficient administration of sulfapyridine and its sodium salt. The blood concentration of the drug during the first days was high. The amount of drug lost by emesis is not known. In the presence of a disease which has a fatal expectancy, chemotherapy should be carried out energetically.

3. Apparently the only symptom of sulfapyridine toxicity was the vomiting. Administration of intravenous blood and saline solution may have played its part in protecting against more serious toxemia. Frequent studies of blood and urine permitted us to observe the patient's response to the drug.

4. The decision to adopt conservative treatment of the evident right mastoiditis depended upon (a) the fact that intravenous sodium sulfapyridine was available and being administered and (b) that reports from the literature⁶ advise against surgical interference in like circumstances.

We express appreciation to Dr. W. W. Spink of the University of Minnesota for the supply of sodium sulfapyridine which was made available for our use in this case.

SUBDIAPHRAGMATIC ABSCESS*

Report of Case

F. C. SCHULTZ, M.D., F.A.C.S.

Saint Paul, Minnesota

The patient, a married woman of forty-seven, complained of a pain in the right abdomen on my first visit, October 26, 1935. She talked constantly in a rambling sort of way due to the fact she had been recently drinking gin and not eating food.

On examination there was a marked tenderness over the gall-bladder region but the abdomen otherwise was normal and the chest was normal.

A few days later the sclerae were jaundiced and she developed hallucinations, seeing fantastic objects in the room. She was then sent to the hospital, where we found the leukocyte count 12,000; temperature 101, and pulse 110. The pupils were pin point in size at this time as well as at my first visit. The Widal reaction was negative. The Schilling test showed a degenerative index of 50. The right posterior base of the chest was then dull and the x-ray examination showed a right lower lobar pneumonia.

During the following month her condition became gradually worse. X-rays of the chest were made repeatedly and showed an increase in density in the right chest, but whether this was above or below the diaphragm was uncertain. The heart was pushed to the left. There was a generalized edema of the whole back. The abdomen became distended, tympanitic and showed the presence of fluid. A lower lobe pneumonia then also developed in the left lung.

The leukocyte degenerative index rose to 73. Blood chemistry values for creatinine, urea and urea nitrogen were normal. At no time was the cough a distressing symptom. The patient took nourishment well and had good elimination.

On November 28, 1935, something happened. She developed a nausea and vomited. She then became dyspneic and had cold perspiration with the pulse up to 134 and respiration of forty. Severe pain developed in her upper right abdominal quadrant.

The next day a re-ray of the chest was made, which showed that the right diaphragm was raised to the level of the sixth costal interspace. The heart was markedly displaced to the left, the apex being pushed to the left chest wall. The outline of the right diaphragm could be made out 7.5 cm. higher than the left. Above the diaphragm was still unresolved pneumonia and some fluid. The x-ray diagnosis was, besides the pneumonia still present, fluid under the diaphragm, a subphrenic abscess.

Operation.—On November 30, 1935, under spinal anesthesia (spinoan 1.5 c.c.) a three inch incision was made just below and parallel to the costal border. Upon entering the abdomen considerable free fluid was found. The upper surface of the liver presented with no sign of intestine, stomach or omentum. The high position of the diaphragm, according to the x-ray, and the low position of the liver indicated there must be a marked interposition of fluid between the liver and the dia-

phragm. With a syringe and needle we punctured the area above the liver and got some cloudy fluid, which was cultured. (This revealed pus cells and after a week the culture showed a micrococcus tetragenous.) With blunt dissection we broke through some adhesions above the liver to be met with a gush of at least 500 c.c. of fluid. After the release of this fluid the liver immediately receded upward to its normal position and now we were able to visualize the gallbladder, which was very large and acutely inflamed. The gallbladder was opened and contained thick inspissated bile and five small gallstones. A rubber tube drainage was established. Two drains were placed above the liver and the incision was closed.

Postoperatively the bile drainage was satisfactory. Her temperature ranged from normal to 101° and her condition was considered fair.

On the ninth postoperative day a pyocyanous infection developed which was quickly corrected with boric acid powder.

The patient continued to improve and left the hospital on December 30, 1935. The bile drainage stopped ten days later. She continued to run a fever for twenty more days. Recovery followed and an x-ray taken on May 27, 1936, showed the diaphragm in normal position.

Discussion

This case proved of interest from a diagnostic standpoint. There is no question but that the alcohol consumption was beyond moderation and left its damaging influence upon her resistance. With a marked icterus of the sclerae, a dark brown urine and upper right quadrant pain, gall-bladder disease was obvious, but operation could not be considered because of the delirium present. The first improvement came in three days when her delirium cleared, but this was immediately followed by a pneumonia of the right lung base without a chill or cough, soon followed by a pneumonia of the left base. During her whole illness she exhibited so little cough that there was no suspicion of pneumonia. The cause for the persistent pin point pupils during the first week of illness was obscure as she denied having taken any drug, and the pupils remained pin point for days in spite of the abstinence from all opiates. Here we have a number of lesions above and below the diaphragm, consisting of a peritonitis, ascites, cholecystitis, cholelithiasis, subphrenic abscess, right pleuritis, right and left bronchopneumonia. This constitutes an extensive involvement in which mortality is high. It would seem that the forerunner of the process was the cholelithiasis. Whether a stone had passed through the cystic and common duct is of no great moment, but there was a cholecystitis of low grade, with a cystic-duct obstruction. The icterus was caused either by a temporary common-duct stone obstruction or a cholangitis. There was no common duct stone palpable at operation and there has been no gallstone attack since, a lapse of over four years. Up to this point we frequently see this clinical picture. The enigma begins here. The gener-

*Presented before the Saint Paul Surgical Society, January 13, 1938.

alized tender abdomen with a moderate tympanitis was confusing. Although we were dealing with a peritonitis yet there was no peritonic ileus. In five days the icterus cleared and the urine cleared, yet the peritonitis and the blood picture indicated an increasing toxic state as shown by the increase from 50 to 70 toxic cells in the Schilling test.

Now the drama scene changes. While we were watching for the mental bewilderment to clear up, by giving food instead of alcohol, bronchopneumonia of both lung bases developed. This continued for weeks with the temperature never rising over 103. She was in a delirium the greater part of the time. Although at times there was a low urine output of 200 c.c. a day, normal blood chemistry values were reassuring.

After two weeks the scene again changed. The abdomen, instead of being tympanitic, had a dull note and was large. A water impact was present. Elimination was satisfactory. The development of the ascites was concomitant with the rising of the density level in the chest x-ray. But why? What was the process? Then suddenly after exactly one month in the hospital, a turn to the worse occurred. There had been no cough, cyanosis or difficulty in breathing, and the patient had taken nourishment well and had been having no pain of any consequence. Then followed a severe pain in the upper right quadrant, nausea, vomiting and a marked dyspnea. There was outspoken resistance over the gallbladder region. A re-ray now showed the density level extending one rib higher, near-

ly to the sixth rib. Because we found only a small quantity of sterile fluid at a former needle puncture of the chest, we agreed with the diagnosis of the x-ray department of a subphrenic abscess. Spinal anesthesia was chosen. Anesthesia was perfect, although we were operating high at the diaphragm. The incision was very short and parallel to the costal margin, giving us full benefit of the incision length. It was a rare picture to see the dome of the liver presenting in the incision and none of the usual abdominal contents. Much of the ascitic fluid of the abdomen escaped as we were studying our plan of attack. It then became clear that this imprisoned fluid above the liver was a part of the general peritonitis. For weeks, adhesions had been forming and had very successfully divided the abdomen from the area between the liver and diaphragm. The impounded peritonic fluid above the liver was now our subphrenic abscess. After the evacuation of the fluid, the field has entirely changed. The very distended gallbladder, the origin of all the trouble, demanded attention despite our anxiety to do little because of the bilateral pneumonia. Although the incision was very short, yet we could readily do a drainage operation. Some questions remain puzzling. Was the pneumonia an extension by lymphatics from the abdomen or was it due to the usual cause of upper respiratory infection? Why should there be a general peritonitis when we did not find any gallbladder perforation? Although convalescence was slow for five weeks, the patient completely recovered and has remained well.

VOLVULUS OF THE CECUM, A POSTOPERATIVE COMPLICATION*

CLAUDE F. DIXON, M.D., and JOSEPH M. MILLER, M.D.

Rochester, Minnesota

Complications of any type may occur in the period following abdominal operations. Intestinal obstruction, both acute and subacute, referable to a variety of causes, will occasion severe apprehension on the part of the surgeon. Adhesions or inflammatory conditions subsequent to abdominal surgical procedures account for the majority of interruptions of intestinal continuity. Response to conservative treatment, emphasizing the principles of intestinal intubation as outlined by Wangenstein and others, is exceptionally effective in many instances of complete or incomplete occlusion of the intestine.

Obstruction of the bowel, referable to rarer etiologic agents, also may occur and, as far as the colon is concerned, volvulus may occur in either the sigmoid flexure or ileocecal region. This accident seems to occur when an exceptionally long mesentery is present, the sigmoid being involved much more frequently than the cecum. When a section of bowel undergoes rotation around its mesenteric axis, or occasionally around its own axis, an isolated loop is formed with obstruction at both ends. The vessels supplying the region are also compressed to a varying degree. In addition, increasing distention of the loop causes further impairment to the blood supply by compression of the capillaries. There also is present increased permeability of the intestinal wall and anoxemia, necrosis, and gangrene

are the end-results, unless there is early surgical intervention.

Postulating that an elongated mesentery is present in the right half of the colon, volvulus of the cecum may occur with the twisting in either direction. The direction of the twist depends to a large extent on the degree of mesenteric development present. When the cecum, ascending and part of the transverse colon are found to have a mesentery common with the small bowel, the rotation is usually in a counterclockwise direction. Of fifty cases collected by Faltin, the rotation in thirty-five was counterclockwise and was clockwise in only fifteen. When more development is present and a greater amount of the colon distal to the cecum is fixed, rotation occurs in a clockwise direction more frequently. The displacement of the cecum will depend on the length of the mesentery. At operation, the greatly enlarged distended cecum may be found in any portion of the abdomen, even in the left upper abdominal quadrant.

In acute torsion, the sequence of events is rapid. Pain of a crampy type, rather severe in nature, which is more or less localized in extent, is present. Early tenderness, marked constipation, occasional shock and rapid localized distention are found.

Such a picture, presented during postoperative convalescence, recently has been observed at The Mayo Clinic.

*From the Division of Surgery, The Mayo Clinic (Dixon) and The Mayo Foundation (Miller), Rochester, Minnesota.

Report of Case

Case 1.—A woman, aged fifty-three, had suffered from intermittent attacks of severe upper abdominal pain of colicky character for ten years. Clay-colored stools had been noted, but there was no history of jaundice. The colics had not been severe for two years prior to registration at the clinic. A qualitative food distress appearing especially after ingestion of fatty foods had been constantly present. Results of physical examination were normal save for moderate diastasis recti and a small umbilical hernia. Pelvic examination revealed a relaxed perineum, a lacerated and slightly eroded cervix, and a retroverted uterus.

Roentgenographic studies of the gall bladder, following the administration of dye, showed the organ to be non-functioning and to contain stones. The abdomen was explored through an upper right rectus incision with the patient under the influence of spinal anesthesia. The gall bladder showed chronic inflammation, contained stones, and was removed. The pancreas, stomach, duodenum, and appendix were explored and were considered normal. The uterus, enlarged to about four times normal size, was in a position of retroversion.

Convalescence of this patient was without incident until the evening of the fourth postoperative day, at which time she complained of mild lower abdominal pain. Examination of the abdomen revealed no abnormalities. She was examined at frequent intervals during the following four or five hours. Five hours after the onset of symptoms the patient's distress became increasingly severe and the pain, at this time cramp-like in character, seemed extremely severe. A distended mass was found in the lower portion of the abdomen to the right of the midline. The body temperature was 99° F. (37.2° C.). The pulse was only slightly elevated. Catheterization was carried out to rule out the possibility of a distended bladder. Volvulus of the sigmoid was considered likely and preparations for operation were made.

A low midline incision was made and on opening the peritoneum, a large amount of serosanguineous fluid escaped. The cecum was markedly enlarged and was free. Volvulus, including the terminal portion of the ileum, cecum, and part of the ascending colon, was present, with torsion amounting to two complete turns in a clockwise direction. Embarrassment of the circulation to the twisted bowel had progressed to such degree that the bowel appeared gangrenous. The cecum, purple in color, had exceedingly thinned walls and one of the longitudinal bands had ruptured. The most conservative procedure seemed to be exteriorization of the entire volvulus and this was done. Clamps were applied to the normal part of the colon distal to the volvulus, and to the ileum proximal to it, and the twisted bowel was amputated by cautery. Twenty cubic centimeters of coli-bactragen was poured in the peritoneal cavity and the abdominal layers were closed around the exteriorized loops of bowel.

Therapeutic aids employed during the immediate postoperative course included a transfusion of blood and the placing of the patient in an oxygen tent. The

ileum was punctured immediately proximal to the clamp twelve hours postoperatively. The patient, rather ill for a period of a week, made an excellent recovery.

Subsequently, the spur between the loops of ileum and colon was destroyed by means of clamps, and closure of the fecal fistula was carried out four weeks postoperatively. On final dismissal of this patient six months postoperatively, the wounds were healed except for a small amount of discharge at the site of closure of the intestinal stoma.

The mortality accompanying volvulus of the cecal region is reported to be high. Chalfont was able to collect 118 cases and he added one of his own. Twenty-three of the patients were not operated on and all twenty-three died. Of the remaining ninety-six who were subjected to some type of surgical procedure, fifty-seven, or 59 per cent, died. The total mortality, both operative and non-operative, was 67 per cent.

When the condition occurs as a complication following a recent operative procedure, the mortality necessarily would be expected to be somewhat higher than if volvulus had occurred primarily. Only two instances of torsion of the ileocecal region following an operation have been found in the literature. In the case reported by Nelson, in which volvulus occurred on the fourth day after a pelvic operation, untwisting of the bowel and performance of cecostomy on the tenth day resulted in cure. Likewise, the patient of Jellinghaus recovered after reduction of volvulus on the sixth day following cesarean section. The condition had occurred on the previous day. It is unusual that these two patients and the one reported in this paper all recovered.

A careful follow-up in the postoperative period of any operation is extremely necessary. With the advent of symptoms suggesting interruption of intestinal continuity, proper treatment must be instituted immediately. A fortunate result attended such therapy in the case reported herein.

HISTORY OF MEDICINE IN WINONA COUNTY

WINONA City was called Wabasha Prairie in 1852. It was not a town, but merely a favorable town site, which had been used until the year before as an Indian camping ground. Of the few buildings there, Goddard's was the best known, the most popular and commodious. Settlers considered themselves fortunate if they could get in at Goddard's during the sickly season, for they felt sure of kind attention and watchful nursing on the part of Mrs. Goddard. The extremely high water of the early spring was followed by low water accompanied by hot and dry weather. This occasioned a general epidemic of severe forms of malarial disease which in many cases was fatal. Wabasha Prairie and the colony at Minnesota City were seriously affected by it, and there were no physicians there at the time.

All summer the heat and drouth continued, and the miasma which spread from the sloughs and large marshes in the immediate vicinity of Minnesota City rendered that locality particularly unhealthy. Serious bilious diseases afflicted the settlers, who, coming for the most part from the eastern states, were unacclimated and lacked the protection of suitable dwellings. A large majority of them were incompetent and unsuited for pioneer life.

Domestic treatment and patent medicines were generally depended upon. One of the colonists was attacked with intermittent fever, for which a neighbor recommended quinine. A friend who had business in Saint Paul was asked to procure a pound or two. Upon his return, the astounded patient received but four ounces and a bill for twenty dollars. After strongly condemning the Saint Paul druggist, he called in his neighbor who had prescribed the medicine. The explanation followed: It was a dram or two he had recommended instead of a pound or two. The sick man, relating the incident, said: "I knew nothing about the stuff. Anyway, it was no serious mistake because it was needed in the settlement and the neighbors took it off my hands without any pecuniary loss."

Every settler in that colony was said to have suffered from an attack of fever and ague. Only fourteen deaths occurred there in 1852, however, and a majority of these were juvenile cases.

A case of what was supposed to be cholera was reported in May, 1852. William Christie came down from Minnesota City, or Rollingstone as it was then called, to meet a new settler who was to arrive at Wabasha Prairie. On his way he forded the back slough, and without changing his wet clothing lay down to rest, complaining of not feeling well. He was taken with cholera and died before morning. Immediately following this, another death occurred at Minnesota City, which was also said to be cholera.

It was estimated by an early settler that the population within the present limits of Winona County on the first day of January, 1853, was about 350. Drs. Bentley, Balcombe, and Childs had come to the county before the close of 1852, so the rapidly increasing population was not entirely without medical attention at this time. However, Childs probably never practiced his profession, but engaged in the mercantile business for a year or two at Wabasha

Prairie. Balcombe came on an exploring trip in 1852 and again in 1853. The next year he built a house on his claim and lived there until his death in 1856. Apparently Balcombe had no intention of establishing a medical practice at Wabasha Prairie. Although poor health prevented him from being prominent, he took an active interest in the development of that part of the territory and in the political questions of his day. A contemporary said that he was a man of the most extended information of any among the early settlers and one of the first and best of the early citizens.

Dr. Bentley spent the winter of 1852-1853 at Minnesota City, then made his permanent residence at the town that is now Utica. There he became postmaster and justice of the peace. The postmaster's job entailed putting the mail in an old trunk where it was available to whoever wished to sort it out; and being justice of the peace was not much more exacting. A marriage ceremony performed by Bentley in 1857 was typical of his easy way of doing business. The principals were ordered to stand up and join hands, then the doctor said, "By virtue of the authority vested in me by the territory of Minnesota, I pronounce you man and wife." Considering the lightness of his other duties, there must have been ample time for him to practice his profession, but it is doubtful whether he made the most of it.

The first permanent, practicing physician in Winona County was Dr. James M. Cole, who arrived in Winona in 1854, and remained there forty years. He had finished his medical education eight years before in New York state. He was always a respected family physician and a substantial citizen, and served as a member of the school board, as city and county physician, and as a member of the legislature. He was also a prominent Mason and Odd Fellow.

Dr. Cole ran a livery stable during the depression of 1857, but he gave it up after four years. Accompanying his new card which appeared in 1862, the editor of the local paper published an article which reads as follows:

"The attention of persons in need of medical attendance is directed to the card of Dr. J. M. Cole elsewhere. He is a pioneer of this place, and in an extended practice and strict attention to his profession has been able to learn the peculiarities of this climate and the wants of invalids. Volunteers' families will find his name among physicians who offer gratuitous service."

The year 1855 marked the beginning of the period of Winona's growth. During the summer several newspapers began publication in Winona City, and printed the cards of newly arrived physicians, notably those of Norton, Chambers, and Farrington. Dr. J. C. Norton, physician and surgeon, justice of the peace, land surveyor, and coroner, resided at Homer.

Farrington, who settled at Winona City, announced in his card that he was prepared to attend to all calls within the village or country and also that he would pay particular attention to diseases of the eye. However, Farrington stopped practicing. After engaging in the hardware and later the drug business, he again took up his profession at Huron, Dakota Territory, in 1880.

In the year 1856, after the territory lying west of Winona had been opened to settlement, Winona grew considerably. Nine physicians practiced there at the time. The combination of the drug business with the practice of medicine was frequently found to be profitable. Dr. Chambers engaged in wholesale and retail drugs from the time of his arrival, and so did Dr. D. Ferris, who came in 1856. A newspaper article of that year gave a good description of the druggist's stock.

"We called on our friend Dr. Chambers the other day, and he laid before us a dish of fresh honey, the first we have seen in Minnesota, and the most palatable we ever tasted. Those who are fond of luxuries will do well to call and get a portion before the rapidly disappearing stock is exhausted. The Doctor has a most extensive stock of Drugs and Medicines—rare fancy articles for the toilettes of the sex divine, and some splendid Manilla and Spanish Cigars for the lovers of the grateful weed."

Evidently the drug business has seen considerably less change in the last century than has the practice of medicine.

Those physicians who thus established themselves in business were infinitely more fortunate than those who met the depression of 1857 with only their practice as a means of livelihood. Although the locality was growing rapidly, nearly every physician was forced to engage in some other business. Dr. Farrington started a hardware establishment; Drs. Moore and Sheardown, arrivals of 1856, became a jeweler and a baker, respectively, and Dr. Cole, as has been remarked, ran a livery stable.

These conditions continued for nearly three years. Eight or ten new physicians came to the county early in 1857, but few had the courage to come in fifty-eight and fifty-nine. During this time, patent medicines and guides to longevity were rife, although it is impossible to say how extensively they were used. Neighbors recommended cures for one another such as cranberry poultice for erysipelas, strawberry leaves for diarrhea, or horse-radish applied to the wrist over the pulse for immediate cure of toothache.

Reports often came in of typhoid and scarlet fever in surrounding localities. At the town of Winona, however, there were but four deaths in the year 1858 among a population of about 3,500. Public health and safety were early considered in Winona, which was an unusually well ordered town from the start. Drs. J. D. Ford, C. B. Dayton, and D. C. Patterson were appointed members of the board of health, which was an active organization in 1858. A year later, the following notice was circulated:

"The undersigned, Overseer of the Poor in Winona County, will receive proposals from Physicians for medical attendance upon the poor of said county during the twelve months next ensuing. The lowest responsible bidder will be entitled to the office of County Physician.

GEORGE W. PAYNE."

The physicians were among the civic leaders in the early days. Dr. John D. Ford especially may be mentioned. Ford was a graduate of Dartmouth College and of the Jefferson Medical College (1844). Soon afterward he commenced the practice of medicine at Norwich, Connecticut, where he attained a high position in his profession. After practicing successfully for about eleven years, he sought a climate more congenial to his health, and in 1856 came to Winona. For a time he resumed his practice, which became very extensive. Almost immediately he showed interest in civic affairs and was elected alderman of the ward early in 1857. The same year he became chairman of the trustees of the school districts, and later a director of the state normal school, and one of the county school examiners. He might well be called a pioneer in the interest of the common school system of the city and state.

Not long after his arrival in Winona, Dr. Ford became the agent of several eastern insurance companies, and gave up the steady practice of his profession, which was difficult for a man in poor health. Through his death, which came November 5, 1867, from typhoid pneumonia, the community lost one of its most valuable members.

At the county Democratic and Republican conventions, physicians were in constant attendance, and they were very often appointed to public office. Dr. S. B. Sheardown, among these, came to Winona City in January, 1856, and became a partner of Dr. Cole. Later, after serving in the Civil War, he took up his residence at Stockton. His interest in the development of the village and in its religious and educational growth well qualified him for public office. Twice he was elected to the lower house of the State Legislature and once to the Senate. At various times Dr. Sheardown had an office in Winona City. He also made the first attempt to establish a hospital there. However, his Stockton practice was very heavy and constantly called him back.

Dr. Sheardown was one of the charter members and the first president of the Winona County Medical Society, which was organized in April, 1869. Twice again he served in the same capacity. He died in 1889 while holding this office. At that time he was also treasurer of the State Medical Society, an office he had held for twenty years.

Dr. J. Q. A. Vale of Homer came to the county a few months later than Sheardown. He also was an active Republican and held many public offices, among them that of town clerk and state senator. He was a charter member of the Winona County Medical Society and in 1870 was elected to the Minnesota State Medical Society.

After 1860 the economic depression was alleviated and many physicians supported themselves by their practice alone. There were doctors at Homer, Minnesota City, Beaver, Utica, Rollingstone, and probably elsewhere; but Winona physicians were often called out of town to attend patients in the county. It was a business convenience for two doctors to form a partnership, keeping an office together and having accounts in common. In this way one would always be available in town while the other attended country patients.

The Civil War called many physicians into service in the early sixties. Dr. Dixon of Saratoga, and Drs. Wedel, Sheardown, Mead, and Trenkler of Winona all gained practical experience in the army and returned to practice again after their military service.

Minor epidemics visited the locality in these years. Diphtheria was reported across the river in 1861; measles was prevalent in 1862, and in the same year several deaths from scarlet fever were reported. The following note appeared in the press in 1863:

"That dread-inspiring disease, diphtheria, is said to exist in town to a considerable extent, and several cases have of late resulted fatally. The disease is not a new one. It has been known to the medical science for upwards of 200 years. If a case gets under headway, it cannot be easily overcome by any medical application; and a preventative has been used with good result in places where the disease was prevalent. The German physicians advise the gargling of the throat, every morning before eating and every evening before retiring, with the brine of Holland herring, which can be procured at almost any German grocery. This as a preventative to the spread of disease is recommended on high authority, and in the present emergency it might be well for every parent to take this simple precaution, especially with children going to school."

One may suspect the newspaper editor of having just received the commission for a large advertisement from the German grocery. Nevertheless, diphtheria continued to prevail throughout the county; one family lost six children in the space of thirty-six hours. Occasional cases of typhoid in the county were reported from year to year, but the disease did not become epidemic in any particular locality. Sickness usually occurred at Winona in the month of July, and was

popularly thought to be caused by the excessive warm weather and the imprudence of the people in eating green vegetables.

Unusually warm weather nearly always produced sickness in Winona. The fall of 1865 saw much disease of a bilious character which yielded easily to medical treatment. Spotted fever, a particularly fatal complaint, was epidemic at the same time and several deaths occurred at St. Charles.

Dr. Franklin Staples, who arrived early in the sixties and shared an office with Dr. Ford, was one of the best liked physicians in Winona, and was well known throughout the county. Especially were his services sought in cases of injury where skill in surgery was necessary. As a man of culture and ability, Dr. Staples was an asset to the community. A lecture given by him under the auspices of the Young Men's Literary Society was entitled "The Old Earth." The breadth of subject doubtless presented few difficulties to him for he had served for five years as the head of a boys' school and later as assistant professor at the Maine Medical College. As early as 1865, he was given the position of superintendent of city schools, but he resigned from the office on account of pressing professional duties.

The practice of medicine reached two extremes at this time. There were the well educated men, and those who had gained surgical skill and knowledge in the war; on the other hand there was the worst kind of quackery. Eye and ear doctors with sure cures, many testimonials, and much advertising were numerous in the sixties. Many of the early druggists used the title of "doctor" and probably dispensed as much advice as medicines. There were about thirty physicians in Winona City in 1865 and twice as many in the county as a whole. Patronage was not lacking, for the number of incoming settlers increased even more rapidly in proportion than the doctors.

Early in 1866 the first medical society organized in Southern Minnesota was established. The physicians of Winona City held a meeting at the office of Dr. Staples and organized themselves into an association called the Medical Society of Winona. Regulations were adopted expressing the objects of the society as follows:

1. Improvement in the science and art of medicine.
2. The promotion of regular and honorable practice in the profession.
3. The maintenance of friendly relations and intercourse among members of the society, and with the regular medical profession at large.
4. The maintenance of suitable and uniform prices for professional services, by adherence to a fee table agreed upon by the society.

The members of the society were Drs. Cole, Hebbard, Staples, and Wedel. Dr. Cole was elected president and Dr. Staples secretary and treasurer for the ensuing year. After organization, the society adopted a set of resolutions and by-laws embodying a fee table, and also agreed to be governed by the code of ethics of the American Medical Association.

Cholera claimed many lives in Minnesota in the year 1866. Fortunately Winona was more scared than hurt. Reports came daily of deaths in New York, Galveston, New Orleans, Saint Louis, and later from just below Saint Paul, but the year ended with no fatalities reported in the town. Early in the year, health officials had made a tour of inspection in the city to find out whether the property holders had complied with the city ordinances in cleaning up their premises, whitewashing cellars, disinfecting drains and so forth. Later, editorial comment demanded further action on the part of the board of health. Special reference was made to a small pond in the neighborhood, and it was argued

that the green scum was very dangerous and "apt to infect the whole community with cholera." A campaign was even effected against rats and the people wholeheartedly rid the city of as much vermin as could be lured into a feed store. Many patent medicines and home remedies were recommended for prevention and cure. Drs. Sheardown and Cole recommended Benson's Rhubarb Cordial to be used in cases of diarrhea or incipient cases of cholera.

A new and more lasting organization of the Winona County Medical Society was effected in April, 1869. Fourteen physicians are listed as charter members: C. S. Sheldon, J. M. Cole, J. B. McGaughey, W. H. H. Richardson, F. Staples, W. J. Youmans, S. B. Sheardown, J. B. Tamblin, H. H. Guthrie, J. Q. A. Vale, A. B. Stuart, Columbus G. Slagel, C. N. Clark, and J. F. Tourtellotte. Of these, the last three were not elected until July. The members of the society were the outstanding physicians of the county. Dr. A. B. Stuart was for many years identified with the history of medicine in Winona. Before coming to this city, he had attended the Lewisburg University and the Berkshire Medical College where he received his M.D. degree. After distinguished service in the Civil War, he graduated from the Bellevue Hospital Medical College and then took up his practice in Winona. While engaged in general practice, he gave especial attention to surgery and had charge of a number of notable cases. He held offices in the Winona County Medical Society, in the State Medical Society, and also in the American Medical Association. In 1872 Dr. Stuart was instrumental in securing the establishment of the Minnesota State Board of Health and became its first president. During the same year, he was elected teacher of surgery in the Winona Preparatory Medical School and soon after held the office of president of that institution. Dr. Stuart practiced until 1877 in Winona and then moved to California in an attempt to improve his health.

Dr. James Brown McGaughey received his early education in private and public schools and in the McDonough Presbyterian College in Illinois. When a youth of nineteen, he enlisted in the army. During his many varied war experiences, he found time to follow his bent for medical studies, and his reading was guided by his brother-in-law, Dr. A. B. Stuart. After the war, he attended Berkshire Medical College at Pittsfield, Massachusetts, and subsequently completed his course at the University of Michigan in 1869. Soon afterward he came to Winona, and entered upon forty-one years of continuous practice of his profession. Dr. McGaughey became a successful physician and surgeon, and was reputed an authoritative diagnostician. His work was characteristically progressive. He made frequent trips to the best hospital clinics and was a tireless reader of professional literature. He was active in state, local and national medical societies and helped to incorporate the Winona Medical School.

Dr. W. J. Youmans, who later edited the *Popular Science Monthly*, practiced in Winona City during the years 1869 and 1870. He had graduated from the medical department of the University of New York, taking special instruction under Professor Draper. Soon afterward he went to England to pursue physiological studies in the laboratory of Prof. Thomas H. Huxley. While there he and Professor Huxley jointly published *The Elements of Physiology and Hygiene*, the treatise on hygiene being Prof. Youmans' work. Returning to America, Dr. Youmans soon came to Winona, where his brothers had a drug business.

(To be continued in May issue.)

President's Letter

THE annual meeting of the Minnesota State Medical Association will be held in Rochester on April 21, 22, and 23. The entire program for the first day will be presented by the Rochester doctors together with a paper on "Arthritis" by Dr. Cecil of New York as their guest. The programs for Tuesday and Wednesday will be by physicians from various parts of the state together with guest speakers of national reputation from other states. These guest speakers will include such men as Fred L. Adair of Chicago on "Obstetrics," John O. Bower of Philadelphia on "Appendicitis," Harry Mock of Chicago on "Head Injuries," A. J. Lanza of New York on "Pneumoconiosis," Norman Jolliffe on "Nutritional Deficiencies," Bernard Nichols of Cleveland on "Radiology," and others; Paul Magnuson of Chicago will bring the fracture symposium to a close with a paper on "Fractures of the Neck of the Femur" (femoral neck).

An outstanding feature and one that is proving very popular in other states is the Round Table discussions; there will be ten of these luncheons each day, those on Monday being conducted by the Rochester group, and on Tuesday and Wednesday by the guest speakers as well as by leaders on various subjects in our own state. At the annual meeting in Michigan and also in Wisconsin last year those who did not register in advance could not get in for lack of space. Each member will be given a card to fill out designating his choice for these Round Table luncheons and it will be wise to register your choice in advance as the accommodations will be arranged according to the applications filed.

The meeting this year will be held in the new Auditorium in Rochester. (Ours will be the first large meeting to use this beautiful new building which was presented to Rochester by the Mayo Brothers.) This building is commodious, well arranged, and but a short walk from the hotels. There will be ample space for the fine scientific exhibits and also for the advertising displays; the cinema films on various scientific subjects will be shown in an adjacent room.

Keep up-to-date by attending our annual meeting. The latest information on a large number of subjects will be given there.

BERTRAM S. ADAMS, President
Minnesota State Medical Association.

BUSINESS MANAGER
J. R. BRUCE

Volume 23 APRIL, 1940 Number 4

ANNUAL STATE MEETING

THE time has come for another annual state medical meeting, the program of which appears in this issue. The three-day meeting takes place Monday, Tuesday and Wednesday, April 22, 23 and 24, 1940, at Rochester, Minnesota.

The Scientific Committee, composed of President Adams, Past President Earl, Executive Secretary Rossell and Dr. W. A. O'Brien, have arranged an attractive program, including a number of out-of-state visitors. Monday will be

devoted to a program of addresses and Round Table discussions by Mayo Clinic dictors with the Mayo Foundation lecture by Dr. Russell L. Cecil of New York in the afternoon.

Entertainment in the form of open house will be provided the visitors at the Mayo Civic Auditorium, Monday evening, by the Mayo Clinic and the Olmsted - Houston - Fillmore - Dodge County Medical Society. This is the first time a medical meeting will have been held in the new auditorium presented to the city of Rochester by the Mayo brothers.

The banquet, Tuesday night, will be held at the Rochester State Hospital, and will be addressed by Governor Stassen and Mr. B. H. Ridder of the *Saint Paul Pioneer Press and Dispatch*.

Enough said—except for the golf tournament to be held Sunday, April 21, at the Rochester Country Club, open to all state association members.

These same dates are also the occasion for the annual meeting of the Women's Auxiliary of the State Medical Association. Mrs. A. C. Baker, of Fergus Falls, president, announces that Mrs. Rollo K. Packard, Chicago, president of the National Auxiliary, will attend the meeting. A full program for visiting auxiliary members has been provided by the local auxiliary group.

A perusal of the program will convince lethargic members that the addresses, scientific cinemas and exhibits, and the opportunity to renew old acquaintances and to make new ones, will be well worth the sacrifice of three days away from the grind.

CHILDREN OF DIABETIC MOTHERS

OBSTETRICS in diabetic mothers has not become an easier problem since the development of insulin because there are more pregnancies in diabetic women who often were sterile in pre-insulin times, or died before they were able to have any children.

Although it has been known for a long time that the children of diabetic mothers are beset by grave dangers—ante partum as well as post

partum—one has the impression that very little thought is given this problem and that no definite plans are made as to the care of these infants during the immediate post partum period.

For years we used to think that a diabetic woman improves greatly during pregnancy, apparently receiving some insulin from the fetus. Although there have been several cases that needed much less insulin during pregnancy than before, it cannot be said that *most* women show such an improvement. It is true that very often there is a very normal pregnancy up to the sixth month, but after that the obstetrician has a right to expect the mother to become a serious problem. Edema, albuminuria, or rise of blood pressure may make their appearance at any time with resulting danger to mother and child.

The child of a diabetic mother may present the following serious problems: high mortality, gigantism, congenital defects, hypoglycemia.

The high mortality is due mainly to stillbirths and asphyxia neonatorum. This has been known for a long time, but the reason for this has not been clear. In a relatively recent article (1939), Priscilla White explains the frequent occurrence of these accidents by extra-diabetic factors—based on her own investigations, as well as those of Murphy (1933) and Smith and Smith (1935, 1936, 1937). More than 30 per cent of diabetic mothers develop pre-eclamptic toxemias, and it has been established that an “excess of serum prolan precedes, predicts and perhaps causes” these toxemias. It seems that the high percentage of stillbirths is not directly related to the diabetes as such, or to diabetic acidosis, but shows definite relationship to the pre-eclamptic toxemias. Patients with normal serum prolan values developed no pre-eclamptic toxemias and there were no miscarriages; those with supernormal values had pre-eclamptic toxemias or miscarried. As proof of this theory she was able to show that patients with supernormal values of prolan responded to replacement estrin and progestin therapy. None of nine patients treated in this manner developed a progressive toxemia, normal prolan values were restored, and none had a miscarriage. All fetal and neonatal deaths in her series of thirty-four cases, except one, occurred in women with abnormally increased prolan values. White concludes that the rise of prolan indicates an abnormal balance, and the

placenta is destroyed as a defensive mechanism. Incidentally, of course, the fetus dies and miscarriage is the result. Although the series of cases is relatively small, the figures seem to be significant: fetal or neonatal mortality in cases with high serum prolan without specific treatment, 50 per cent; in cases with normal prolan, 8 per cent; and in those with high prolan but specific treatment, 11 per cent (1 of 9 cases; this mother received definitely less and apparently insufficient replacement treatment).

Gigantism in children of diabetic mothers has been reported for about half a century, and has usually been attributed to the hyperglycemia of the mother. This theory has been adhered to up to now. White, however, cannot find any correlation between the size of the infant and the control of the mother's diabetes. She suspects that this too may have its cause in the abnormal hormone balance, because she found the larger infants usually in the cases with high serum prolan, who had no specific treatment. Snyder (1934) and Hoopes (1934) were able to produce a similar picture in rats and rabbits by means of prolan injections: miscarriages, stillbirths, oversized fetus, etc. Statistics show that 18 per cent of the children of diabetic mothers weighed at birth over 10 pounds (Skipper, 1933), and that 60 per cent weighed over 8 pounds (White, 1935). All ten cases of hypertrophy and hyperplasia of the pancreas, collected by Rascoff et al. (1938), weighed 9 pounds or more.

The prevalence of congenital defects in infants of diabetic mothers is not readily noticeable because of the relatively small number of diabetic mothers, but when larger series of cases are examined, one is surprised to find that the incidence is about twice that of control cases (Skipper, 1933; Joslin, 1937). As diabetes apparently is genetic in origin, there may be some relation of this factor with the higher incidence of congenital defects (Joslin).

Hypoglycemia in the newborn of a diabetic mother is a grave condition, and may easily lead to death. In fatal cases, hyperplasia and hypertrophy of the Langerhans islets have been demonstrated in a number of cases. The first case to be fully published was that of Dubreul and Anderodias (1920). In 1938 Rascoff, Beilby and Jacobi collected ten cases—their own and those published between 1920 and 1936. The

islet tissue was found greatly increased; it varied from four to six times to twenty to thirty times that of a normal pancreas. Other microscopical changes were peri-insular edema and fibrosis and eosinophilic infiltration of the stroma between islets and acini and sometimes of the stroma within the islets. Of other organs, the adrenals were found affected in two cases (hemorrhage and necrosis), and the liver was enlarged in one case. All mothers suffered from severe, often uncontrolled, diabetes, except one who was found to have a latent diabetes. That there is no definite correlation between the blood sugar level and the insular size was shown very recently by Helvig (1940). It is logical to assume that the etiologic factor for this hypertrophy is the hyperglycemic state of the mother.

The symptomatology is not always very definite. Often the dominant symptoms are twitching and convulsions, but these are not always present. At other times the dominant symptom is cyanosis, as was the case in Randall and Rynearson's group of seven children of diabetic mothers (1936). Among these seven, only one showed twitching and convulsions, and that child had a normal blood sugar. Occasionally there may be no symptoms with a blood sugar as low as 45 mg. (Skipper).

Hypoglycemia may be due to adrenal hemorrhage alone. Of course it is most difficult to differentiate it from the hypoglycemia due to hyperinsulinism, especially if the mother has diabetes. Both may exhibit acute onset with symptoms of shock, followed by collapse and death within twenty-four hours. Usually, however, the symptoms of adrenal hemorrhage do not appear until thirty-six to seventy-two hours post partum, and there is usually high fever and very rapid, shallow respiration. The damage to the adrenal gland in itself seems to make the organism more sensitive to insulin, and the severest picture can be expected when hyperinsulinism and adrenal damage occur in the same infant.

It is also not an easy task to differentiate hypoglycemia from other pathologic conditions of the newborn—asphyxia, cerebral hemorrhage, etc. It seems a good rule to investigate the blood sugar when the child is large and difficult to resuscitate by aspiration and inhalation of carbon dioxide and oxygen. Cerebral conditions

usually respond slowly. There is marked depression of the sensorium and the reflexes, and there may be a characteristic cerebral cry or whine. Hypoglycemia responds more rapidly and the child has a good cry once respiration is established, and there is a good sucking reflex until coma supervenes.

The treatment consists of rapid supply of dextrose by various routes until the blood sugar rises to a fairly normal level, and all dangerous symptoms disappear. Higgons (1935) used 100 c.c. of a 5 per cent glucose solution subcutaneously, and some physicians used blood from the mother because of the high sugar content. Randall and Rynearson (1936) were able to deliver successfully and guide through the newborn period eight successive children born to diabetic mothers. The treatment varied somewhat with every case, and was guided by the symptoms, the blood sugar, and the ability to retain feedings by mouth. First, the infant should receive all the treatment necessary to establish normal respiration—aspiration, oxygen with carbon dioxide, etc. The length of time the child should be kept in an oxygen-carbon dioxide or oxygen atmosphere depends on the child's respiration. Ten per cent dextrose is administered intramuscularly (5 c.c. in each buttock). A blood sugar determination should be carried out as soon as possible, and further intramuscular injections may be given at intervals of one or more hours if indicated.

Feedings in form of 10 to 20 per cent dextrose solution can be started after two to four hours and repeated every one to two hours for the first day, or even longer. The oral treatment with dextrose solution and the time when a formula with a high carbohydrate content should be started depends on whether or not the infant is able to retain feedings.

Closest observation is essential for at least two to three days in cases that show definite symptoms, particularly as we are not able to say how long there is danger from a complicating hypoglycemia. Repeated blood sugar determinations by a micro-method should be done and the treatment continued until all symptoms have disappeared and the blood sugar level is no longer dangerously low.

It is of the greatest importance to make plans for the newborn of any diabetic mother *before the child is born*. The laboratory should be

ready to make a sugar test on the cord blood or the child, and if this is not possible, dextrose should be administered as a precautionary measure.

Of even greater importance is the obstetrical problem during the last few months of pregnancy. The diabetes should be controlled by all means. A slight tendency to show less sugar for a while should not lead to a radical reduction or even cessation of insulin, because of the undue strain upon the fetal pancreas and the possibility of a hypertrophy under such conditions. Hormone treatment to restore hormonal balance probably will be treatment for the prevention of toxemias and consecutive miscarriage or intrauterine death. The same type of treatment may reduce the number of over-sized children. But until such treatment is put on a practical basis, White's contention (1935) that "the premature delivery of the fully developed though chronologically premature infant of the diabetic mother by cesarean section is the obstetrician's successful answer to the challenge" should be kept in mind. Randall and Rynearson, who stress the same idea, recommend the thirty-sixth to thirty-seventh week of pregnancy for this purpose.

ROBERT ROSENTHAL, M.D.

CABOT CRITICIZES AGAIN

THE article entitled "Give the Patient a Break" by Dr. Hugh Cabot, which appeared in the *American Magazine* for April, doubtless caused resentment in the minds of most physicians who happened to read it. It savors too much of washing dirty linen in public, and certainly is an addition to the present-day propaganda to discredit not only the present system of private practice but also the profession in general.

The rank and file of the profession will concur with the author in his attitude toward certain medical practices which he decries. Fee-splitting is one. Exorbitant fees in respect to the patient's ability to pay is another. This is a relative matter, however, for a fee of \$100 may be excessive for one patient and one for \$10,000 may conceivably be too small for valuable service rendered to one who pays a million dollar income tax. An excessive fee, whether it be \$100 or \$10,000, if it is more than the patient should

be charged, is condemned by the majority of doctors. The bad practice of overcharging is not a valid reason for condemning the fee system.

The author thinks the fee system all wrong, and cites his own experience in charging large fees as proof. If in his own early experience he overcharged, his self-condemnation is justified—not the system.

Group practice is the thing, according to the author. But he is not sure whether the general practitioner can be dispensed with. His contention that the specialist is necessary, is admitted by all. Even his contention that a specialist may see only his specialty, is admitted. This depends, however, on his professional attainments, not on his being a specialist. Others believe in the advantages of medical groups in the practice of medicine. Whether such groups actually lower the cost of care to the patient, is open to argument. The independent doctor can still obtain consultation without difficulty. That the general practitioner can and does care for most medical needs is a fact.

The evils associated with self-styled specialism have long been recognized by the profession and much progress has been made in remedying them. Lack of standards for determining qualifications for specialists were lacking in former days, but have been established by the profession itself. There is no present need for a member of the profession shouting from the housetops about a situation which is being remedied and which never was a major evil.

The author's main cause for disgruntlement is what he claims to be the opposition of medical societies to the prepayment plan of providing for medical care. Is this an accurate statement?

The American Medical Association has given much thought to the whole subject of methods of payment for medical service and has been consistent in its attitude.

In 1934 the House of Delegates took the stand that medical service should be paid for by the patient according to his income status and medical service should have no connection with cash benefits.

In 1935 the same body reaffirmed its opposition to compulsory sickness insurance, whether conducted by a governmental unit or an industrial body. It encouraged medical organizations

to establish plans for providing medical care by voluntary budgeting to meet costs of illness. It also stated that there is nothing inherently good or bad from a medical point of view in different methods of collecting medical fees, providing they are kept separate from any control of practice.

The American Medical Association has been wrongly accused at times of opposing hospital group insurance. Only unsound features of certain plans were criticized.

In 1938 the House of Delegates advocated the principle of cash benefits to members of insurance groups for medical or hospital service in order that the relationship of the patient to the physician or hospital be not disturbed.

This record shows that the national organization is not opposed to prepayment plans *per se*, but is strongly opposed to plans that disturb the fundamental requirement of free choice of physician, place the control of medical care in other hands than the medical profession, and, by insufficient financing or otherwise, result in inferior medical care.

The medical profession has been striving for years, and is today more than ever trying to solve financial problems associated with medical practice, just as more thought is being expended today on economic problems in general. It seems at least poor taste for Dr. Cabot to discredit publicly his own profession in what is doubtless an altruistic attempt on his part to point out a way to provide better medical care at more reasonable cost.

AUTOMOBILE ACCIDENTS

LAST year 32,100 human beings were killed and 1,210,200 were injured, many severely, as a result of automobile accidents. The fatalities are about the same as in 1938 but the number of injured has increased by some 64,000.

A parade with 32,100 people in line is a big parade. If this number of people were killed at one time and in the same place, the newspapers and radio would make headline material. If this number were lost in one battle the toll would make a deep impression. Scattered throughout the land and throughout the year, as these accidents are, one is little impressed by the figure unless someone near and dear to him

has been the victim. Even an injury from an automobile accident makes some impression.

What are we going to do about it? Fatalities from other types of accidents have been greatly reduced in recent years, but the toll for automobile accidents remains about the same high figure.

The problem is much the same as in the care of a disease exacting a large death toll. Find the cause and a campaign of education will bring certain results.

Insurance companies have been active in publicizing the subject of automobile accidents. We doubt whether a reduction in such accidents would result in any pecuniary benefit to insurance companies. But we do know that such a reduction in accidents would mean money in the pockets of all who now carry such insurance. The greater the hazard, the more individuals feel compelled to carry insurance, but the insurance companies do not pay for the deaths, injuries and destruction to property. We do. With fewer accidents, fewer policies would be written, even though the rates were lower.

The Travelers Insurance Company of Hartford has just issued a booklet entitled "Smash Hits," which is an analysis of the automobile accidents of 1939. We hasten to do our bit in calling attention to some of the causes of accidents incident to the driving of automobiles. Being both a pedestrian and driver at times, we will not take sides as to who is most to blame. About the same number of both are killed each year.

Haste and carelessness are the causes of most accidents. Lack of good manners is as often as not the cause of accidents.

More than half the fatalities occur after dark when there is only a quarter of the traffic as in daylight. Too, half of the fatalities among pedestrians occur in those over sixty-five years of age. The conclusion is obvious that drivers do not slow down sufficiently after dark. Loss of keenness of the senses and agility in older individuals make this group particularly susceptible to automobile accidents.

Attention should not be centered on haste and carelessness alone in an effort to remedy the present situation. A hundred and one additional steps can be taken to minimize the possibility of accidents. Speed laws, traffic regulations, rules of the road, periodic checking of brakes, severe

punishment for drunken driving—all merit attention. As in many similar problems, education and an aroused public opinion will do much to reduce the high price we pay for a great convenience.

In Memoriam

Louis Guinard

1864-1939

The death of Guinard, September 5, 1939, just when France was being mobilized for the war, brought lasting grief to thousands in spite of their preoccupation with national affairs. Among them were physicians who treated tuberculosis, his friends and pupils, as well as the patients whom he had brought back to health. In the hearts of the French people he had a place similar to that filled by Trudeau in America. His entire life was devoted to one great task, the alleviation of the suffering caused by tuberculosis. The fact that France has produced such men gives us hope for the future of the world at a time when violence is rampant and the world is on fire.

The first sanatorium in France, Mangini at Hauteville, was opened by his friend Dumarest in 1896. Bligny, in the valley of the Chevreuse, admitted its first patients in August, 1903, with Guinard as director. It was for the common people of Paris and had one hundred and twenty beds. He remained there until his death. He had no other ambition than the health of his patients and the success of the institution. Drolet and the writer visited him there one pleasant Sunday in 1917. We were invited to dinner and sat with the patients as he always did. Most of the patients were soldiers. Afterward we saw them reclining in the liegehallen or long porches. We met Mme. Guinard and finally bade the doctor good-bye at the front gate where he had come, not only to see us off but to wish God-speed to the many relatives and friends of patients who were visitors that afternoon.

Dr. Marcle visited Bligny later and became a close friend of the Guinards. To all of us his life has been an inspiration.

A. T. LAIRD.

Leonard J. Nilles

1902-1940

Dr. Leonard John Nilles of Rollingstone, Minnesota, died at the Winona General Hospital on February 2, 1940, of rheumatic heart disease.

Dr. Nilles was born at Rollingstone, Minnesota, on July 24, 1902. He received his grade school education in Holy Trinity Parochial School at Rollingstone, following which he attended Holy Trinity High School, from which he was graduated. His pre-medical training was received at St. Mary's College at Winona, Minnesota. In 1931 he enrolled in the University of

Minnesota School of Medicine, from which he graduated in June, 1935. He spent a year of internship at St. Mary's Hospital in Minneapolis, following which he entered general practice at Rollingstone, Minnesota, where he continued to the time of his death.

On June 18, 1935, he was married to Miss Mary Bochnak of Minneapolis. He is survived by his wife, a brother, Arnold, and two sisters, Hattie and Viola.

Dr. Nilles was a member of the American Medical Association, Minnesota State Medical Association, Winona County Medical Society and the Southern Minnesota Medical Association. He was a member of the Knights of Columbus, Council 639, of Winona, Minnesota, St. Nicholas Society of Rollingstone and the Rollingstone Civic Club, of which he was president. He was known as a sincere, honest and conscientious practitioner and was trusted and regarded highly by the people of his community and his fellow practitioners.

Fred H. Stangl

1893-1940

Dr. Fred H. Stangl died March 19, 1940, following a four weeks' illness of subacute bacterial endocarditis. He died in the St. Cloud Hospital where he was a member of the staff and also pathologist.

Doctor Stangl graduated from the University of Chicago and Rush Medical College in 1918 and served his internship in the Cook County Hospital, following which, he served as pathologist for the Cook County Hospital for three years. In 1922 he came to St. Cloud where he has been in practice since that time.

He was a member of the Nu Sigma Nu Fraternity. During the World War he served as consultant to the Naval Training Station in Chicago.

During his practice he was a member of the Lewis-Stangl Clinic, St. Cloud, where he was associated with Dr. C. B. Lewis, Dr. W. L. Freeman and his brother, Dr. P. E. Stangl.

He was a member of the Stearns-Benton County Medical Society, Minnesota State Medical Association, a Fellow in the American Medical Association and an active member of the American Society of Clinical Pathologists. He made various contributions to literature on influenza during the 1918-1920 epidemic and on the growth of the tetanus bacilli.

Correction.—Attention is called to an error in the section on History of Medicine in Hennepin County, which appeared on page 181 of the March issue. In the list of Commissioners of Health for the City of Minneapolis under the year 1919, statement was made that Dr. H. M. Guilford died. The information in parentheses should have read: (*Dr. H. M. Guilford resigned December 15, 1919. Dr. Elizabeth Woodworth took his place temporarily until his successor, Dr. F. E. Harrington, took office January 1, 1920.*) According to latest reports Dr. Guilford is living in Madison, Wisconsin, where he is associated with the State Board of Health.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association

W. F. Braasch, M.D., Chairman

COUNTY OFFICERS MEET

County officers met in discussion groups according to their interests this year instead of according to district groupings.

The result was some lively discussions of current economic and welfare problems of Minnesota, most of which were summarized neatly and provocatively by discussion leaders as follows:

Medical Relief

Dr. W. A. Coventry, Chairman, Committee on Low Income and Indigent Problems: Our relationship with Director Walter Finke of the Division of Social Welfare is good. With the aid of his medical advisory committee, I believe he will eventually straighten out the relief tangle in Minnesota and insist upon sound, uniform policies all over the state.

Tough Committee

In the meantime, you will be interested in the plan worked out in one county as a substitute for a county doctor plan. This plan was just outlined for us by one of the men who has helped to engineer it. In this county, the doctors arrived at an agreement with the county welfare board whereby all the doctors in the county were to take care of welfare patients for a sum that would not exceed the amount paid before to two county doctors and one township doctor, the first year. They established a fee schedule and a tough working committee of doctors to audit medical bills and supervise the service. The doctors got 60 per cent of normal fees for medical work, 40 per cent of normal fees for surgical work. Physicians were required to itemize their bills. If the record was not complete, the bill was cut. Hospital cases were taken care of in their own community as far as possible. A strenuous effort was made to get the disabled back to work. Last year, the cost to the county for caring for seventy-five people locally was \$2,650.00, while the cost of caring for 18 cases at the University hospitals was \$1,662.00.

When a group of doctors can agree on a workable plan and see that it is put into effect as these men have done it is quite a hopeful sign.

There were many hopeful findings in the return on the questionnaire concerning medical relief plans sent out all over the state last month under the auspices of the Committee on Low Income and Indigent Problems.

Drift to Free Choice

For instance, the drift is definitely to free choice of physician in handling of relief work in Minnesota. Only seven contact committee members reported county doctors.

Seventy-five per cent of the counties are using the old SERA fee schedules. Reductions from normal prevailing fees varied on these reports from 10 to 60 per cent. The majority were between 40 and 50 per cent. Need of a universal fee schedule seems obvious from this questionnaire. Fees for some surgical operations vary from \$100.00 to \$200.00. The average for hysterectomy was found to be \$150.00; for gall bladder \$100.00; for tonsillectomy \$15.00; and for hospital obstetrics \$15.00.

Most of those who responded are dissatisfied with the township plan of handling care for the indigent.

In most cases authorizations are secured from the county welfare board. In other cases, authorizations were secured from any official, up to the mayor.

For State-wide Campaign

L. R. Critchfield, Chairman, Committee on Immunization and Vaccination: It is essential that we make a concerted state-wide effort to push vaccination and immunization of children in our state and the first step is undoubtedly a survey of the extent to which these measures are now being pushed by county medical societies. When we have this information, which, we hope, will be available for the State Meeting, then we want to draw up a standard method which will be available to every county in the state for this work. Every possible assistance will be given by the committee to foster this effort.

Overcrowding and Senility Problem

Dr. George Earl, Chairman, University Relations Committee: The current situation in the state institutions is very briefly as follows:

There are 500 beds in the University hospitals and they could use 5,000. Hundreds of hernia cases, tonsillectomies, prostatectomies are on the waiting list, and undoubtedly these cases should be cared for at home.

Tuberculosis sanatoria are not overcrowded; but the tuberculosis problem of the other state institutions, especially the institutions for the insane, is acute. A separate tuberculosis institution is needed for care of these patients. More coöperation between the tuberculosis institutions and private physicians is needed also, in after-care of discharged patients.

The School for the Feeble-Minded at Faribault is overcrowded and many of its cases have been transferred to the Colony for Epileptics at Cambridge with the result of over-crowding at the Cambridge Institution also. Institutions for the insane are being filled up with the senile cases. Beds are two feet apart in some institutions, and in all of them the senile, who are multiplying with the extension of our life span, are crowding out the younger people for whom treatment might be effective. We are going to have to lay out more money for care of the older insane.

The inebriate problem also complicates the condition in our nervous and mental institutions. These cases should be removed from the state hospitals and sanatoria and placed in state workhouses, where they could support themselves.

For Professional Get-togethers

Dr. J. M. Hayes, Minneapolis, Chairman, Committee on Inter-Professional Relationships: The first chairman of the Inter-Professional Committee, Dr. F. J. Savage, put the committee on our map but was unable to get far with the promotion of inter-professional meetings in the individual counties. We know, in Hennepin County, the value of such get-togethers. Our "Economics Club" is now some years old and it has been very effective in handling some of our Hennepin County problems.

This year, we are hoping to see that there are more such meetings throughout the state. We have already sent out letters to the secretaries following a meeting of the state committee last month. We are going to follow up those letters until some action is achieved.

Hospital Building

Dr. L. L. Sogge, Chairman, Committee on Public Policy: There are two bills for hospital building in Congress now: one, introduced by Senator Wagner of New York, for emergency building of hospitals in communities which can operate but cannot construct such institutions; the other introduced by Senator Mead of New York for a larger appropriation to be made available as needed for construction of hospitals and other sanitary projects and facilities and also to provide funds for operations if they are needed for a period up to four years.

"We Feel More Kindly"

We feel more kindly toward Senator Wagner as a result of his new bill than we did before. His program is fine in theory, but I, myself, cannot see how any community, which is so poor it cannot build a hospital, will be able to keep a hospital going. The proposal brings up many questions. Will there be physicians to staff the hospital in these communities or will it be necessary to import them? If a hospital is built as suggested and the community fails to live up to standards or fails to support the hospital, will it then revert to the government and be run by the government as a federal medical institution for civilians?

I do not know of any community in Minnesota that could make application for a hospital of this kind. It seems to me far better to arrange for assistance to already existing hospitals so as to provide for occupancy of already existing beds.

Objectives Should Be Supported

Dr. R. G. Leland, Chicago, Director, Bureau of Medical Economics, American Medical Association: The profession of medicine should view the entire situation which has led to current legislative proposals with understanding and sympathy. Objectives should be supported but the means to achieve the objectives should be carefully considered. I doubt if any of us can speak with certainty about the new federal hospital building proposal until we know just what the relationship is to be between the federal government and local control. If the hospital is not operated to conform with standards of the federal government it might, indeed, revert to federal control.

I believe we should explore every other possibility for building of any urgently needed hospital without the investment of federal funds. We should thus avoid any possibility of competition with church and voluntary hospitals. Certainly, we must proceed cautiously and study carefully anything, however attractive it may be, which might eventually carry with it federal control for care of the sick.

Fracture Program

Dr. R. G. Webb, Chairman, Committee on Fractures: By means of active fracture committees, whose chairmen are members of a state-wide fracture committee, we are hoping to establish a state-wide program for better first-aid in fracture cases in Minnesota. We need better transportation for fracture cases; also, better hospital equipment for care of these cases, better x-rays and, finally, better post-graduate education in the handling of these cases.

A part of the program must be carried on with public groups of all kinds. Lay training in first-aid is essential. It is equally essential that all ambulances be required by ordinance to carry proper equipment. Good emergency fracture equipment can be constructed for \$1.10 (10 cents for iron and \$1.00 for labor). But our educational program must not stop there. Technicians need instruction in taking of radiographs and we, ourselves, need to discuss our cases freely in hospital staff meetings, eliminating all personal feeling so that we may learn from each others' experiences.

Fractures present one of our most serious problems. The problem cannot be met without an active state-wide program and uniform methods.

"We Seek from You"

Mr. Walter Finke, Director, Division of Social Welfare: We offer you our whole-hearted coöperation in the solution of the medical problems of relief and social welfare. We seek from you every help you can give us.

Our medical problems are among the most important that we have before us for solution. We believe

that, for the best result, government agencies and doctors must get together.

Since the re-organization went into effect last July, we have been studying all our expenditures. For instance, we have been able to cut our staff from 560 to 285. We are trying now to find out if five per cent, for example, is the right percentage to pay out of relief funds for medical care. We are also studying every phase of our medical program with the Medical Advisory Committee of doctors selected from among a list submitted by your association. Our object is to aid and educate the County Welfare Boards upon whom the final responsibility rests. In dealing with the county welfare boards, we must depend, as you know, upon coöperation and education rather than any mandatory right.

New Methods Developed

The principle of decentralization which applies here is sound, I am sure, and good progress can be made within our present set-up. We have developed new methods of procedure for the medical care of several groups which come within the province of the Division of Social Welfare in coöperation with the Medical Advisory Committee. We are now starting on procedures for recipients of Aid to Dependent Children. What we do on this matter as on all other procedures involving medical care will be done only with and through the Medical Advisory Committee.

Learn by Reading

Dr. William A. O'Brien, Director, Post-Graduate Medical Education, University of Minnesota:

We hear a great deal about the educational value of the radio; but the amount of learning actually absorbed by ear is small unless it is supplemented by reading and fosters reading.

The principal means of post-graduate education for doctors are post-graduate courses, private reading, and consultation.

In the future there will be two types of people—those who do and those who do not continue their formal education after their under-graduate training is completed.

Realization of this fact is indicated in the large number of bids for continued education which come to us nowadays from older age groups.

We need to continue our studies because of the influx of new knowledge which began about twenty years ago and continues without a pause.

Gaps Must Be Filled

There were gaps in the undergraduate education of all of us which must be filled in addition to keeping all of our information up to date. In so doing we are obliged to combat tendencies to indifference and ignorance and a feeling that "the old stuff was good enough." It is the essence of medicine in a democracy that every man should have the opportunity to be aware of every new thing.

It is encouraging to know that we can go on learning into our seventy's. As we grow older, we

tend to lose, not the ability, but the desire to learn.

The commonest excuses heard among doctors for not taking this or that course are: "too busy," "can't get away," or "patients need them." To those who give the last named excuse we sometimes say: "Think how many might live because you went away."

Remarkable Growth

So far, 2,120 have registered for medical and hospital courses of three days to a week at the Center for Continuation Study. Growth of interest among hospital personnel in these courses has been remarkable. The Center has proved its worth as a new method of providing intensive post-graduate education in the guise of a professional vacation. As such, it is unique in the United States, but there are other methods of post-graduate education which should not be neglected. Reading is better than listening and writing is better than reading. We should keep up on the medical journals and the new monographs. Incidentally, packets offered in connection with the State Medical Association's subject-of-the-month programs offer a valuable aid to professional education as well as to public health education and everybody should send for them.

In the midst of a busy life, the late W. J. Mayo found time for an hour's reading of the medical journals every day. Obviously, a regular program of reading pays.

There are two ways to improve our public health; of course, one is by police power, the other is by constant voluntary individual improvement in the practice of medicine.

THE COUNCIL MEETS

The Minnesota State Medical Association will have a representative at the United States Pharmacopœial convention for the first time this year.

Decision to send Dr. Raymond N. Bieter, University of Minnesota, official delegate from the association, was made by the Council at its February 23rd meeting with a view to securing an adequate representation of medical men at this important convention.

Doctors in Minority

The United States Pharmacopœial convention meets once every ten years for the purpose of setting standards for old accepted drugs and for new drugs that are to be introduced into medical practice. Pharmacists and pharmaceutical manufacturers are well represented at these conventions but physicians and medical schools, both of whom are equally interested in the deliberations, are sometimes in the minority. Dr. Bieter will confer with Dr. A. E. Osterberg of Rochester, and Dr. E. J. Fogelberg of St. Paul, the

other official Minnesota delegates, and with Alternates J. L. Bollman of Rochester and F. G. Benn of Minneapolis as to policies and procedures of the convention.

Insurance Policies Studied

Several questions were submitted concerning provisions of policies written by the large companies for malpractice insurance in Minnesota. The Council reemphasized a fact which seems to be the source of some misunderstanding among members, that the Minnesota State Medical Association has never officially endorsed any policy for malpractice insurance.

Several reputable insurance companies write malpractice insurance in Minnesota. The policies of all these companies will be studied and a report made to the House of Delegates.

May Advertise

County medical societies may sponsor local advertising campaigns on modern medical service and the function of the family doctor, if the members vote their approval. A series of advertisements prepared by a Minnesota newspaper man was submitted to the Council for its information and the Council voted again to leave it to the county medical society to determine local policies on such matters. Only one stipulation was made—that the copy be carefully read and approved by the doctors.

* * *

Special publicity campaigns launched in connection with the opening of hospitals or other community projects involving the doctors were also judged to be a matter for local determination and supervision.

Epilepsy Organization Incorporates

Articles of incorporation for a new voluntary health education agency were presented by Dr. D. E. McBroom of Cambridge for the information of the Council. The new organization will foster research in epilepsy and at the same time try to extend public understanding of the disease. Many physicians are interested in the new organization, Dr. McBroom said, and every effort is being made to see that activities of the new society are kept under proper supervision and control.

WOMEN SHOULD KNOW

The active interest of large women's organizations in the Wagner Health bill has persisted in spite of the fact that the bill has never been reported out of committee and a new hospital bill has ostensibly taken its place in the affections of its promoter.

It is clear that a concerted drive to press the women's organizations for definite action on this bill, or at least on the general provisions of the National Health program, is in progress.

It is, of course, entirely proper that American women should inform themselves on important national issues such as this one. If the American people are in grave need of sweeping reforms in the care of the sick and of tremendous new appropriations for the public health, the women should know about the need and work for them.

On the other hand, if the proposed legislation endangers something very precious to Americans and if the vast appropriations will achieve, principally, the establishment of new government bureaus, at a heavy cost to future generations, with no assurance of practical aid where aid is needed, then American women should know about that, too.

Outlines Distributed

Mimeographed outlines of the report of the President's Inter-Departmental Committee, including the report of findings of the WPA Health Survey and of the Wagner bill which aims to correct the situation, have been prepared and are already being distributed among club-women in Minnesota.

No official action has ever been taken by the largest of the women's organizations, the Minnesota State Federation of Women's Clubs, on the subject. Officers of the organization have conferred with representatives of the Minnesota State Medical Association on the matter and are well informed on the policies for Minnesota of the doctors and the public health officials of the state. They have asked for a companion piece expressing this policy and indicating actual needs and how they can be met in Minnesota for distribution to their members. This material is now being prepared and will be available upon request.

Easy Appeal

It is easy enough to make an appeal to a group whose professed interest is public welfare and particularly the welfare of the women and children, on the basis of an alleged need for medical care.

Backers of the National Health Program in toto are quick to seize upon the genuine idealism of such groups as a means of persuasion.

Physicians who explain the attitude of medicine toward the whole problem must speak in terms of idealism, also—but of a sounder idealism which cherishes the fine things already accomplished, which preserves human dignity, safeguards orderly progress and protects it from the heavy hand of politics.

Women should know that you cannot bring about a millennium by passing a bill and making an appropriation especially in the field of health. Improvement in our national health depends upon many factors, and ample facilities for medical and hospital care constitute but one of them. A clear understanding on the part of everybody about what makes a healthy people and how progress in medical science and the control of disease are achieved should be the objective.

DOCTORS CAREY AND SHIPSTEAD SPEAKING

Minnesota dentists, last month, brought to the Twin Cities one of the most vigorous and picturesque of all medical orators, Dr. Eben J. Carey, Dean of Medicine at Marquette University.

During his stay in Saint Paul, Dr. Carey talked to the dentists at their annual meeting on government medicine; he spoke on the radio and he addressed the regular Open Forum of the Chamber of Commerce. Reverberations are still heard in widening circles from his pungent and vigorous remarks.

Senator Henrik Shipstead, guest of honor, also chose to express himself in unmistakable opposition to government operation of medical and dental services at the dentists' meeting. A unique occasion—take it all in all—and one which showed how indissolubly linked are the future of medicine and dentistry and how closely their thinking and their policy parallel the policy of organized medicine.

Befuddled Legislation

Some characteristic excerpts of the remarks of both Dr. Carey and Senator Shipstead are given below:

DR. CAREY: A lot of befuddled legislation is being presented for passage in Congress these days and in our state legislatures. All of it is based on the premises that the cost of medical care is too high in America and that medical care is inadequate.

I challenge both premises.

Americans are the healthiest people ever seen any time, anywhere. Their health depends upon healthy minds and souls as much as upon healthy bodies.

"You Cannot Buy Health"

You cannot go out and buy five dollars' worth of health. And by the same token, you cannot purchase health by immense appropriations of money if, at the same time, you take away the dignity and rights of the human being.

A series of bills was introduced in the Wisconsin legislature a few years ago which would have fastened compulsory sickness insurance, worse than anything in Europe, on the state of Wisconsin. They said there was an acute need for such legislation; but apparently the acute need was really for the doctors and the dentists to put a little emotionalism into the presentation of their own objectives—because we stopped the Beimiller bills by only six votes!

Milwaukee is Healthier

As a result of that vote, however, we made an extensive study of medical care in Wisconsin and we sent Mr. Crownhart to Europe to investigate the European systems after which Beimiller had patterned his legislation. We found that the Irish and the Germans in Milwaukee are far healthier than the Irish in Ireland or the Germans in Germany.

Nothing in Europe could compare with our system of medical care in Milwaukee, Wisconsin, or in any other center of the United States.

Since 1929, we have had bankruptcy in government in the United States and yet there are people who would crowd our bankrupt government into the administration of medical care to the sick.

Bait for Politicians

In America we have a constitution and a Bill of Rights. We determine our course by mutual cooperation, not by paranoid dictatorships. We should understand what a sickness tax will and will not mean. In the first place, it will mean graft because a sickness tax is too big a bait for any politician. In the second place, it will not mean better health. If it did mean that, there would be better health in Europe than there is today.

In any case, health is not an end in itself; it is a means to an end. The purpose of medicine is not to generate healthy brutes but to aid in the generation of healthy, well-balanced human beings, and the souls of

human beings are more important than their bodies! Never should we forget that many magnificently healthy people have crippled bodies. Many who have contributed most to our welfare have suffered from incurable ailments.

To make people believe that you can buy health over the counter—so much health for so much money—is to put false ideas into their heads.

Only True Advance

The only true advance in health as in any other department of life comes by education and coöperation. It is true that in America we sometimes confuse freedom with license. Sometimes we forget that our freedom carries with it responsibilities. Dentists and medical men have accepted those responsibilities in the past. They will continue to accept them in the future if government does not step in to take away that freedom.

"We Are All Human"

SENATOR SHIPSTEAD: All of us are agreed, I believe, that good care must be made available to all who need it. Some think that government should control and finance such care. Others are equally positive that while the government must aid in financing the care of the indigent, if the government attempts to control and regulate all care for the sick, both medicine and dentistry will deteriorate.

For my part, I incline to agree with these others. I have seen people who are assured of a salary no matter what they do to take care of a sick patient. I know what happens when the incentive to excellence is removed. We are all human and won't be anything else, God help us, until further notice. . . .

Unemployment Must Be Removed

On the other hand, I do not believe that our present condition can be permanent. Unemployment is like an economic cancer which must be removed or our economy will collapse. But, I believe that we can and will remove it, that ultimately we shall find work for all so that they can take care of themselves.

We must face facts as they are, however, and not as we wish them to be. We do not stand still; we move on, one way or the other.

Over the Line

It is that tendency which we must take into account in the field of public health and medicine. Heretofore, government has occupied itself chiefly in setting standards. Shall it now make the important step over the line into actual operation of the care of the sick?

I believe it must not. I believe that government must levy taxes to pay for care of the poor and I believe that government must continue to fix standards; but I also believe that actual operation of medical care must be left to the men who are trained in the basic

sciences. I do not believe that government bureaus can care for the sick.

Senator Shipstead is the only representative of the healing profession in the Senate. As such and as senior senator from Minnesota, he was presented with a memorial from the Minnesota State Dental Association at this meeting.

"A LEOPARD'S SPOTS"

(Monthly Editorial Prepared by the Medical Advisory Committee)

Since the time when man first began to think and evaluate things, the question of heredity or environment as an answer to the difference in the nature and actions of people has been a moot question.

Why is it that starting with a given personality and heredity tendencies and adding to these a professional education—medicine, law or any other—one man will search for the better things in life while another will find his level in the lower strata of both thought and society? Having once found the level of his environment the chances are overwhelming that he will continue at that level. Criminal tendencies which grasp men who have found the lower levels make it impossible for them to rise out of them. Educational advantages many times seem further to militate against such a change.

Are we, as members of our Association and supposedly in the upper level of society, lowering ourselves in the estimation of our clientele when they find us not only associating with but condoning the criminal acts of certain of our profession by urging their retention in medical circles?

If the writing of an unnecessary number of narcotic and liquor prescriptions is cause for censure, if the performing of criminal abortions is punishable at law, then your Medical Advisory Committee believes that when men convicted of these crimes testify in Court, especially in malpractice cases, their testimony should be considered of the same level of veracity as the standard of their practice and that men in our Association should think twice before urging their retention in our noble and honorable profession. That you cannot change a leopard's spots no matter what the nature of his environment, goes without saying.—B.J.B.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

Court Declares Mistrial in Case of Chiropractor

Re State of Minnesota v. Arthur J. Kolling.
On March 21, 1940, after three days of trial, Judge W. W. Bardwell declared a mistrial in the prosecution of Arthur J. Kolling, chiropractor, 805 LaSalle Avenue, Minneapolis. The defendant's lawyer stated that the defendant was seriously ill with ptomaine poisoning and under the care of Dr. W. A. Bessesen, physician and surgeon. A statement from Dr. Bessesen was presented to the Court. Judge Bardwell promptly declared a mistrial and discharged the jury.

The defendant, who is not licensed to practice medicine in the State of Minnesota, but who holds only a chiropractic license, owns and operates the Hennepin Clinic at 805 LaSalle Avenue, Minneapolis. He was indicted by the grand jury of Hennepin County on May 16, 1939, on a charge of practicing medicine without a license. The indictment grew out of testimony that the defendant sutured a wound of a ten-year-old boy who had been injured by an automobile at 8th and LaSalle Avenue, Minneapolis, and was taken to the office of the defendant prior to the arrival of the police ambulance. The accident occurred on April 14, 1939, and on April 28, 1939, the defendant sent the family a bill of \$25 for "services rendered."

Kolling was first placed on trial on this indictment in June, 1939. The jury deliberated more than twenty-six hours and stated to the Court that it was unable to agree. It was reported to be deadlocked 6 to 6. The present trial was a re-trial of the same indictment.

Kolling pleaded guilty in the District Court of Hennepin County in 1928, to a charge of practicing medicine without a license and was fined \$150. In 1938, he pleaded guilty in the United States District Court at Minneapolis to an indictment charging him with a conspiracy of violating the Internal Revenue laws of the United States. He was fined \$2,000 on this charge and upon the payment of this fine, a two-year prison sentence was suspended for a period of three years.

Physicians Licensed February 9, 1940

January Examination

Anderson, Bruce Murat—Stanford U., M.D. 1938, Rochester.

Arack, George—U. of Minn., M.B. 1939, Saint Paul.

National Board Credentials

Johnson, John Woodrow—U. of Minn., M.B. 1938, M.D. 1939, Kerkoven.

OF GENERAL INTEREST

The Minnesota State Medical Association study subject for April is "Cancer of the Digestive Tract."

* * *

Dr. M. H. Larson of Nicollet has opened an office at Waconia for the practice of general medicine and surgery.

* * *

A new directory of graduates of the medical school of the University of Minnesota has been compiled by the *Minnesota Alumni Weekly* office. It replaces a directory issued in 1936.

* * *

Dr. John A. Knights of Bemidji has been appointed Assistant Division Surgeon of the Great Northern Railroad, the division taking in the territory from Duluth to a point west of Bemidji. Dr. Knights is associated in practice with Drs. McCann and Johnson.

* * *

Dr. Albert Balmer, who has been associated with Dr. E. F. McElmeel at Pipestone since June, 1939, opened an office of his own on March 1. He is now located in the offices formerly occupied by the late Dr. Thomas Lowe.

* * *

Rochester was host to approximately twenty-five surgeons from several southern states at a meeting of the Southern Society of Clinical Surgeons, March 27-29. Dr. Charles W. Mayo and Dr. John M. Waugh of the Mayo Clinic arranged the three-day program.

* * *

Dr. Joseph G. Pollard of Hanover, New Hampshire, is spending his sabbatical leave at the University of Minnesota studying methods of teaching personal and public health in the Arts college and also studying the university athletic injury program.

* * *

Dr. Jerome Hilger and Helen Backer, both of Saint Paul, were married January 20, 1940. They have recently returned from their wedding trip in the east and are at home at 37 Inner Drive, Highland Village, Saint Paul.

* * *

Dr. M. E. Maun, pathologist at Saint Joseph's Hospital, Saint Paul, since 1938, has been appointed Assistant Professor of Pathology at the Wayne University Medical School, Detroit, Michigan. Dr. Maun received his medical degree from Northwestern in 1936.

* * *

Dr. Reed M. Nesbit, Head of the Division of Urology at the University of Michigan, will inaugurate the Franklyn R. Wright Lectureship in behalf of the Twin City Urological Society with a lecture on "Hypertension in Unilateral Renal Disease." The lecture will be given at the University of Minnesota. Details will be furnished later.

* * *

Dr. Albert V. Stoesser, associate professor in the pediatrics department at the University of Minnesota,

has been awarded a \$1,000 grant by the Markle Foundation of New York for the support of study of the relation of sodium and potassium balance to asthma.

* * *

The Annual George Chase Christian Lecture presented by the Cancer Institute of the University of Minnesota will be given on Tuesday evening, April 30, by Dr. John J. Bittner, National Cancer Institute Fellow, Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine. Dr. Bittner will speak on "Breast Cancer as Influenced by Nursing." Medical Sciences Amphitheatre, 8:15 p. m.

* * *

Minnesota Medical Alumni and their wives are urged to obtain tickets on registration at the State Medical Meeting for the annual banquet of the Alumni Association. The banquet will be addressed by Dr. Karl Buehler, Professor of Psychology at St. Thomas College and former head of a psychologic institute in Vienna, on the subject of "Hitler and Austria."

* * *

Dr. E. Sidney Boleyn, 76-year-old Stillwater resident and a relative of the famed Anne, told the County Officers' Medical Conference held in Saint Paul in February, that his mother is 104 years old and his father, about ten years older. Both are still living in India, where they are retired civil service employees of the British government. Greatest record for longevity in the family is an aunt who died at 124 years of age and an uncle at 127.

* * *

Dr. Raymond B. Allen of Detroit, a graduate of the University of Minnesota medical school, Class of 1928, has been appointed executive dean of the Colleges of Medicine, Dentistry and Pharmacy of the University of Illinois in Chicago. Dr. Allen, after completing a fellowship in urology at the Mayo Foundation, served as assistant dean of Columbia University medical school and then went to Wayne University medical school in Detroit as dean.

* * *

Dr. Walter C. Alvarez of Rochester is to be the banquet speaker at the annual meeting of the Northern Tri-State Medical Association in Battle Creek, Michigan, April 9. His topic will be "The Patient Who is Always Ailing in Spite of Many Treatments."

In March, Dr. Alvarez addressed the Douglas County Medical Society meeting in Omaha, Neb., and conducted a clinic in the St. Joseph hospital. He also addressed students of Creighton University school of medicine.

* * *

Dr. Adelbert Louis Dippel became associated with the University of Minnesota as associate professor of obstetrics and gynecology, March 1, to fill the position made vacant by the death of Dr. John A. Urner. Born in LeGrange, Texas, Dr. Dippel attended the University of Texas from 1920-28, receiving his B.A.,

M.A. and M.D. degrees. He did graduate work at Johns Hopkins University School of Medicine, where he has been an instructor and associate in obstetrics.

* * *

The Lotus D. Coffman Memorial Silver Service given by physicians who have attended courses at the Center for Continuation Study was formally accepted February 19, when the service was used for the first time.

The ophthalmologists and otolaryngologists two years ago started the fund for the service, which consists of six pieces—a modern tray, a coffee urn of the Georgian period, and four pieces of 1803 Early American solid silver—teapot, creamer, sugar and waste bowl.

* * *

The spring program at the Center for Continuation Study on the University of Minnesota campus, as announced by Dr. William A. O'Brien, follows:

April 1-6—Venereal Disease
 April 29-May 1—Obstetrics
 May 2-4—Health Problems of College Students
 May 6-11—Electrocardiography
 May 20-25—Pediatrics
 May 23-25—Hospital, Medical and Institutional Library Service
 June 6-8—Gynecologic Tumors

* * *

Two members of the University of Minnesota physiology department have been honored with fellowship awards.

Dr. Earl H. Wood, instructor, has been awarded a National Research Council fellowship in the medical sciences to work with Prof. A. N. Richards of the University of Pennsylvania.

Dr. Gordon K. Moe, also an instructor, has been awarded the Porter fellowship of the American Physiological Society to work with Prof. C. J. Wiggers of the Western Reserve University in Cleveland.

* * *

A new hip pocket oxygen flask and a new face mask, developed by Dr. Walter M. Boothby of the Mayo Clinic, Rochester, in cooperation with Captain Harry Armstrong of the army air corps' materiel division at Wright field, were exhibited at the meeting of the Federated Societies for Experimental Biology and Medicine in New Orleans, March 12-18.

The new mask was designed to prevent a pilot from inadvertently committing suicide, if he accidentally opens his mouth at high altitudes; the oxygen flask, to insure pilots of the necessary supply of gas if they are forced to bail out from high altitudes.

* * *

Physicians under thirty-five years of age, desirous of obtaining active duty with the United States Army, are being offered appointments in the Medical Corps Reserve in the rank of First Lieutenant. Wages of a First Lieutenant are \$225.00 a month (\$263.00, if married); that of a Captain \$278.00 a month (\$316.00, if married). In assignments where government quarters are available these amounts are \$40.00 and \$60.00, \$60.00 and \$80.00 per month less, respectively. Many of those under the age of thirty-two who received such appoint-

ments last year took entrance examinations for commissions in the Regular Army. Those in Minnesota interested should apply to the Commanding General of the Seventh Corps Area, New Federal Building, Omaha, Nebraska.

* * *

Physicians for the Panama Canal zone are wanted, there being a need for additional medical service in connection with the construction of new locks, which is expected to take at least four years.

Duties will be to care for health of employees and to give aid in case of accident. There are several well-equipped staff hospitals in the zone. Several Minnesota graduates are in the service.

Candidates must pass civil service examinations. Initial pay is \$4,000 a year; maintenance may be secured in government houses for \$15 to \$30 a month; a trip to New York on an official boat costs but \$30. The average temperature is 85 degrees.

Further information may be had by writing to Chief Health Officer, Balboa Heights, Canal Zone. Gilbert M. Stevenson, Minnesota '28, Dispensary, Gamboa Canal Zone district, Panama Canal, supplied the above information.

* * *

Several members of the University of Minnesota staff presented papers at the meeting of the Federation of American Societies for Experimental Biology in New Orleans, March 12-18.

Dr. Maurice B. Visscher, head of the department of physiology, presented a paper on "Super High Speed Cinematography of the Isolated Heart-Lung," prepared in cooperation with Dr. G. K. Moe, also of the University of Minnesota staff, and Dr. C. Landis of Columbia and Dr. W. A. Hunt of Wheaton college.

Dr. Charles F. Code, assistant professor of physiology, presented a paper on "A Comparison of the Histamine Content of Blood and Bone Marrow." Dr. Code was awarded the Theobald Smith prize for his work on histamine a year ago by the American Association for the Advancement of Science.

Dr. George O. Burr, professor of physiological chemistry, had for the title of his paper, "Limiting Factors in the Biological Synthesis and Chemical Analysis of Fatty Acids."

Two papers were presented by Dr. G. K. Moe and Dr. E. H. Wood. Titles are "Cardiac and Pulmonary Edema in Isolated Perfused Preparations," and "Correlation between Serum Potassium Changes in the Heart-Lung Preparation and the Therapeutic and Toxic Effects of Digitalis Glucosides."

"The Effect of Adrenalectomy on the Deposition in the Liver of Spectroscopically Active Fatty Acids," was the subject of a paper presented by Drs. Richard H. Barnes, Elmer S. Miller and G. O. Burr.

Dr. Ancel Keys, professor of physiology, presented a paper on "The Valvular Efficiency in Mitral and Aortic Insufficiency," which constituted a study of cardiac output by the x-ray kymograph and the acetylene methods, by which means the proportion of blood which leaks back through an insufficient valve can be determined.

MINNESOTA STATE MEDICAL ASSOCIATION

87th Annual Session

April 22, 23, and 24, 1940

Rochester, Minnesota

ANNOUNCEMENTS

Presiding officers at each session have been instructed by the Committee on Scientific Assembly to show a blue light on the speakers' rostrum two minutes before the end of each speakers' program time. A red light will show when his time is up. All meetings are in charge of committee members.

Register and Secure Your Badge at the Registration desk at the Mayo Civic Auditorium at 8 a. m. Registration on Sunday, April 21, will be in the lobby of the Kahler Hotel.

Telephone Service: Special incoming lines have been installed at the Registration desk. All local and long distance calls will be handled promptly.

Bring Your Membership Card: There will be no registration fee for those who present a membership card or receipt or other evidence from their county society or the state association or the American Medical Association nor for interns or members of associated professions including dentists, pharmacists, nurses, hospital personnel or social welfare workers who present invitations or other identification.

Badges: You are requested to wear your badge while you are on the convention floor. This is important and will greatly assist us to eliminate undesirable persons such as cranks and pickpockets who so frequently try to take advantage of meetings of this character.

Women's Auxiliary: Wives of physicians attending the meeting may secure programs of the business and social sessions of the Women's Auxiliary at the Women's Registration Desk in the lobby of the Kahler Hotel. All visiting women are cordially invited to attend special events arranged by hostesses of the Olmsted-Houston-Fillmore-Dodge County Medical Auxiliary. Among these is a tea at Mayo-wood, Monday, April 22. Every Auxiliary member is invited to attend the Annual Meeting and luncheon Tuesday, April 23, at the Rochester Country Club.

Automobile: Good parking space is available without charge east of the Auditorium.

Luncheons: Thirty-two Round Table Luncheons have been arranged for this meeting at Rochester hotels and restaurants, 11 on Monday, 11 on Tuesday, and 10 on Wednesday. Tickets must be purchased in advance for these luncheons. Lists of subjects and leaders are printed in this program. Attendance at each luncheon is limited, and late comers will be accommodated according to their choice if limits have not already been reached. Price of luncheon ticket is 75 cents.

Annual Banquet: The annual dinner for members, guests and their wives will be held at the Rochester State Hospital, Tuesday evening, 6:30 p. m., April 23. Governor Harold E. Stassen and Mr. Bernard H. Ridder of St. Paul, publisher of the *St. Paul Pioneer Press and Dispatch*, will be the banquet speakers. Tickets \$1.25 per person.

The Southern Minnesota Medical Association will present a medal, following its annual custom, to the individual physician who presents the best scientific exhibit at this meeting. Judges will be selected from among distinguished out-of-state visitors. The award will be made at the Annual Banquet, Tuesday night.

Guest Speakers: In accordance with an established precedent, several special societies are sponsoring visiting guest speakers for this meeting. We are indebted, this year, to the following societies:
The Minnesota Radiological Society: Speaker—Bernard H. Nichols, Cleveland, will deliver the society's annual Russell D. Carman Lectureship in radiology.

Northwestern Pediatric Society: Speaker—Paul Louis Schroeder, Chicago.

The Society of Internal Medicine: Speaker—Norman Jolliffe, New York.

The Northern Minnesota Medical Association: Speaker—Harry E. Mock, Chicago.

The Trudeau Society: Speaker—Anthony J. Lanza, New York.

Other speakers appear at the invitation of the Committee on Scientific Assembly.

Open House: All physicians, visitors and their wives will be guests of the Mayo Clinic and the Olmsted-Houston-Fillmore-Dodge County Medical Society at an Open House to be held Monday night, 7:00 p. m. in the Arena at the Mayo Civic Auditorium. Exhibits will be open for inspection and there will be music and special entertainment. Refreshments will be served.

Medical Women's Luncheon: The American Medical Women's Association, Minnesota Branch, will hold a luncheon meeting at the Mayo Foundation House, Monday noon, April 22. All women physicians are invited. Make reservations in advance through Della G. Drips, Mayo Clinic. There will be no charge for this luncheon.

Alumni Dinner: The Minnesota Medical Alumni will hold its annual reunion dinner at 6 p. m. Monday, April 22, in the Kahler Cafe. Tickets at the Registration Desk. Price \$1.25 per person.

Museum: The Mayo Foundation Museum of Hygiene and Medicine, directly across from the Mayo Clinic Building, will be open each day to members and visitors. Hours: 9 a. m. to 12 m. and 1:30 p. m. to 5 p. m.

Physical Therapy Demonstration: There will be demonstrations of Physical Therapy by F. H. Krusen and his staff Monday, April 22, at 10 a. m. and 3 p. m. at the Museum. The Museum lecture room will accommodate only 50 persons, and those who wish to attend should make reservations in advance with F. H. Krusen, Mayo Clinic, Rochester.

Tour and Demonstration at the Institute of Experimental Medicine of the Mayo Foundation: Tours of the Institute and demonstrations of its work have been arranged for Monday, April 22, at 10 a. m. and 3 p. m. Reservations should be made in advance with F. C. Mann at the Institute, Rochester.

PROGRAM—87TH ANNUAL SESSION

Approximately 40 can be accommodated for each tour. Buses leave the Kahler hotel at 9:45 a. m. and 2:45 p. m.

Minnesota Radiological Society: A dinner in honor of Bernard H. Nichols, Carman Lecturer, will be given by the Minnesota Radiological Society at the Kahler hotel cafe Tuesday evening at 6:30 p. m.

Hotels: See enclosed folder for list of Rochester hotels with rates, locations and application blank for accommodations. Detach application blank, fill out and mail. The clerk will forward your application promptly if accommodations are not available at the Hotel of your first choice.

Golf: The annual Golf Tournament of the Minnesota State Medical Association will be held Sunday, April 21, 1 p. m. at the Rochester Country Club, weather permitting.

This is one of the finest golf courses in the country and all medical golfers are urged to participate provided the greens are open. Registrations should be made in advance with J. W. Kernohan, Mayo Clinic, Rochester. Attractive prizes have been donated for the winners.

GUEST SPEAKERS

Paul Budd Magnuson is Associate Professor of Surgery at Northwestern University and attending surgeon at Passavant Memorial and Wesley Memorial Hospitals, Chicago.

Harry E. Mock is Associate Professor of Surgery at Northwestern University, Senior Surgeon at Saint Luke's Hospital, Chicago, and chairman of the Council on Physical Therapy of the American Medical Association.

Fred Lyman Adair is Professor of Obstetrics and Gynecology at the University of Chicago, Chief of Service at the Chicago Lying-In Hospital, and Chairman of the American Committee on Maternal Welfare, the Committee on Prenatal and Maternal Care, White Conference on Child Health, and the American Congress on Obstetrics and Gynecology.

Norman Jolliffe is Associate Professor of Medicine at New York University College of Medicine and Chief of the Medical Service in the Psychiatric Division of Bellevue Hospital.

Bernard H. Nichols is President of the Radiological Society of North America, Chancellor of the American College of Radiology and roentgeneologist at the Cleveland Clinic in Cleveland, Ohio.

Nathan B. Van Etten is President of the American Medical Association, Medical Director, Consulting Physician, and President of the Morrisania City Hospital; President and Visiting Physician at the Union Hospital and Past President and Trustee of the Medical Society of the State of New York.

Paul Louis Schroeder is Director of the Institute of Juvenile Research, criminologist for the State of Illinois, author of several books on juvenile delinquency. He is now engaged in a study, in cooperation with the Department of Pediatrics of the University of Illinois, on emotional aspects of physical disease.

Russell L. Cecil is Professor of Clinical Medicine, Cornell University Medical School, Professor of Medicine, Polyclinic Medical School and Hospital, Associate and Attending Physician, New York and Bellevue Hospitals, Consultant in Medicine, New York Infirmary of Women and Children, Nyack Hospital, Nyack, New York, and Saint Mary's Hospital, Passaic, New Jersey, and Chairman of the New York State and New York City Committees on Pneumonia Control.

Mr. Bernard H. Ridder is publisher of the *Saint Paul Dispatch and Pioneer Press*.

Hon. Harold E. Stassen is Governor of Minnesota.

Anthony J. Lanza is Assistant Medical Director of the Metropolitan Life Insurance Company, Consulting Surgeon of the United States Bureau of Mines and Medical Consultant to the General Motors Corporation. He has conducted special research in industrial hygiene and occupational diseases and especially in the diseases due to inhalation of dusts.

John O. Bower is Director of the Department of Surgical Research, Temple University, Chief Surgeon to the Philadelphia General, Saint Luke's and Children's and Northeastern Hospitals of Philadelphia and Director of the Foundation for Clinical and Surgical Research. Since 1933 he has been Chairman of the Commission on Acute Appendicitis Mortality of the Medical Society of the State of Pennsylvania, and he is originator of the Philadelphia Plan for the Reduction of Appendicitis Mortality.

SCIENTIFIC PROGRAM

Monday, April 22

Morning Session

- A. M.
- 8:00 Visit Scientific and Technical Exhibits
- 8:30 Scientific Cinema.....North Room
Fistulectomy
L. A. BUIE.....Rochester
- 9:00 What's Wrong with the Patient Who is Always Tired?
W. C. ALVAREZ.....Rochester
- 9:15 Facts and Assumptions Regarding the Endocrine Glands
E. H. RYNearson.....Rochester
- 9:30 Medical and Surgical Treatment of Prostatism
G. J. THOMPSON.....Rochester
- 10:00 What's New in Cancer Research?
W. C. MACCARTY.....Rochester

(Intermission)

- 10:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific CinemaNorth Room
The Management of Diabetes
R. M. WILDER.....Rochester
- 11:00 The Sulfamido Compounds: Their Practical Applications in Clinical Medicine
A. E. BROWN.....Rochester
- 11:15 Practical Hints on the Use of Vitamin Preparations
R. M. WILDER.....Rochester
- 11:30 Recent Advances in the Treatment of Diseases of the Liver
A. M. SNELL.....Rochester
- 11:45 Proctological Problems We Don't Like to Discuss
L. A. BUIE.....Rochester
- 12:15 **Round Table Luncheons**
Roentgen Therapy for Inflammatory Conditions
A. U. DESJARDINS.....Rochester
Management of Nephritis
N. M. KEITH.....Rochester
M. W. BINGER.....Rochester
Treatment of Peritonitis
J. M. WAUGH.....Rochester
Oxygen Therapy
W. M. BOOTHBY.....Rochester
W. R. LOVELACE.....Rochester
Arthritis
RUSSELL L. CECIL.....New York City
P. S. HENCH.....Rochester
C. H. SLOCUMB.....Rochester
Anesthesia
J. S. LUNDY.....Rochester
E. B. TUOHY.....Rochester
Peripheral Vascular Disease
E. V. ALLEN.....Rochester
N. W. BARKER.....Rochester

- Diseases of the Blood and Their Treatment
C. H. WATKINS.....Rochester
B. E. HALL.....Rochester
M. M. HARGRAVES.....Rochester
Diagnosis and Management of Common Skin Lesions
P. A. O'LEARY.....Rochester
Management of Urinary Tract Infections
J. L. EMMETT.....Rochester
E. N. COOK.....Rochester
T. L. POOL.....Rochester
Refraction
A. D. PRANGEN.....Rochester

Afternoon Session

- P. M.
- 1:30 Visit Demonstrations, Scientific and Technical Exhibits
Scientific CinemaNorth Room
Recent Traumatic Deformities of the Face
G. B. NEW.....Rochester
- 2:15 Symposium on Chronic Backache and Sciatica Caused by Protruded Intervertebral Disk
M. N. WALSH.....Rochester
J. D. CAMP.....Rochester
J. G. LOVE.....Rochester
- 2:45 **Mayo Foundation Lecture**
Present Trends in the Study of Arthritis and Rheumatism
RUSSELL L. CECIL.....New York City
Professor of Clinical Medicine Cornell University

(Intermission)

- 3:15 Visit Demonstrations, Scientific and Technical Exhibits
Scientific Cinema.....North Room
Complete Rectal Prolapse (Surgical Repair)
C. W. MAYO.....Rochester
- 4:00 Gastric Cancer Masquerading as Benign Disease; Differential Diagnosis; Surgical Treatment
G. B. EUSTERMAN.....Rochester
WALTMAN WALTERS.....Rochester
- 4:20 Symposium on Diagnosis and Treatment of Chest Tumors
H. J. MOERSCH.....Rochester
H. M. WEBER.....Rochester
S. W. HARRINGTON.....Rochester
- 4:50 A Recently Recognized Type of Headache; Diagnosis and Treatment
B. T. HORTON.....Rochester

Evening—7:00 P. M.

- Open House....Arena, Mayo Civic Auditorium
Music, Floor Show, Refreshments
The Mayo Clinic and the Olmsted-Houston-Fillmore-Dodge County Medical Society will be hosts

PROGRAM—87TH ANNUAL SESSION

Tuesday, April 23

Morning Session

A. M.

- 8:00 Visit Scientific and Technical Exhibits
- 8:30 Scientific CinemaNorth Room
Hay Fever
L. E. PRICKMAN.....Rochester
- 9:00 **Fractures**
Presiding: R. C. WEBB, Minneapolis
Elbow Joint
M. H. TIBBETTS.....Duluth
Ankle
M. O. OPPEGAARD.....Crookston
Os Calcis
O. W. YOERG.....Minneapolis
- 9:45 Fracture of the Neck of the Femur
PAUL B. MAGNUSON.....Chicago, Ill.
Associate Professor of Surgery, North-
western University Medical School

(Intermission)

- 10:15 Visit Demonstrations, Scientific and Tech-
nical Exhibits
Scientific Cinema.....North Room
Treatment of Scarlet Fever (in color)
F. E. SCHMIDT.....Chicago, Ill.

11:00 **Pre-operative Care**

- Surgery of the Biliary Tract
E. M. JONES.....Saint Paul
Preparation of the Diabetic Patient
A. H. BEARD.....Minneapolis
Surgery of the Stomach
N. H. BAKER.....Fergus Falls

- 11:30 Skull Fractures and Cerebral Injuries
HARRY E. MOCK.....Chicago, Ill.
Associate Professor of Surgery, North-
western University Medical School

12:15 **Round Table Luncheons**

- Chemotherapy (Sulfanilamide, etc.)
W. W. SPINK.....University of Minnesota
Office Gynecology
J. J. SWENDSON.....Saint Paul
Management of Associated Injuries with
Cranio-cerebral Injuries
HARRY E. MOCK.....Chicago
Medical Management of Gall Bladder
Disease
E. T. HERRMANN.....Saint Paul
Diseases of the Kidney from a Diagnostic
Standpoint
BERNARD H. NICHOLS.....Cleveland
Allergy
A. A. WHITE.....Minneapolis
Management of Peptic Ulcer

There is too great a tendency to observe the early lesion in tuberculosis until progression has actually occurred, in which case the maximum opportunity for cure is lost. The purpose of treatment is not only to arrest the peripheral extension of the lesion but also to arrest the process of central caseation. Otherwise, even though temporary arrest may occur later, the central caseous residue constitutes a menace in future years.—J. Burns Amberson, Jr., M.D., Amer. Student Health Assn., Dec. 1939.

* * *

The steps which lead to the establishment of a former tuberculosis patient in a job are extremely important to the patient himself, to his family, to the people with whom he will be working and to the community at large. They are important to the patient because they may determine whether or not he will live. They are important to the patient's family and his future co-workers because, if his disease reactivates, he may infect them. The community is vitally concerned not only from the standpoint of preventing relapses with consequent infection of others, but also from the economic aspect of protecting the thousand or more dollars it has invested in treatment of the patient.—Mrs. Kathryn M. Pearce, Minneapolis, Minnesota.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR APRIL

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis, Station WLB, University of Minnesota, and KDAL, Duluth.

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program will be as follows:

April 6—Tumors of Stomach

April 13—Tumors of Bowel

April 20—Early Diagnosis of Tuberculosis.

April 27—Tumors of Mouth.

clinic in connection with this course is under consideration.

For further details write J. S. McCartney, M.D., Associate Professor of Pathology.

WABASHA COUNTY SOCIETY

A dinner meeting of the Wabasha County Medical Society was held at the Lake City Hospital on the evening of February 22, to which all physicians in the county and maternity staffs of all hospitals in the county were invited. Dr. B. A. Flesche of Lake City, the regularly appointed representative from this society, gave an outline and stressed the important points of the three-day course of instruction held at the University Center for Continuation Study, February 8, 9 and 10, on the care of the newborn with special reference to prematures.

There were eighteen in attendance, including doctors and nurses.

MAYO CLINIC WEEK

A clinicosurgical week under the direction of The Mayo Foundation will be held at Rochester, Minnesota, May 6 to 11, inclusive. A series of surgical clinics and discussions will be presented with particular emphasis on the treatment of cancer. Visiting physicians are invited to attend.

COURSE IN SURGICAL PATHOLOGY

A course in Surgical Pathology will be given at the University of Minnesota, Department of Pathology, during the first session of summer school, June 17 to July 26, 1940.

This course is designed to give a comprehensive review of the lesions shown in surgical specimens, special emphasis to be laid on the diagnosis of tumors, or lesions which may be confused with tumors. It is arranged according to systems, e.g., gynecology, skin, et cetera. Fixed gross material is used in parallel with slides. Fresh material, as available, is also employed, but obviously may not be strictly applicable to the day's work. X-rays are used in connection with the study of lesions of bones.

About one-third of each class period is devoted to demonstrations on the lantern to show special features. The daily class period is three hours, but for anyone who wishes to do extra work in some field material will be provided.

This course is open to anyone who has finished the regular medical course in pathology, but is especially intended for hospital pathologists and those who wish a course which may aid them in preparing for the examinations of the special boards. Establishment of a

WASHINGTON COUNTY SOCIETY

The regular meeting of the Washington County Medical Society was held March 12, at the Stillwater Club Rooms.

Reports of the meeting of county medical society officers held in Saint Paul in February, dwelling on the care of the indigent and better methods of immunization, were given.

The committee in charge of obtaining donors for blood transfusions stated that members of Post 48, American Legion, will report at the Lakeview Memorial Hospital for grouping and will be on call in case of need.

The chairman of the fracture committee reported the Fracture Symposium of the Hennepin County Medical Society and the Minneapolis Surgical Society of March 7. He called attention to the two motion picture films owned by the Minnesota State Medical Association showing proper first aid and transportation technic for those suffering from fractures of the long bones and demonstrating treatment of fractures of the spine. It was suggested that these films be shown to local firemen, policemen, sheriffs and to any others who might be interested. It was also suggested that inquiry be made into local ambulance service and equipment.

Dr. E. M. Jones, of Saint Paul, gave an illustrated lecture on "The Gallbladder: Its Diseases, Symptomatology, Complications and Treatment." Dr. Jones, who is Counsellor for the Fifth District, discussed the subject of accepting to membership physicians located in neighboring counties, for whom attendance at the Washington County meetings would be more convenient.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of February 14, 1940

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, February 14, 1940. Dinner was served at 7 o'clock and the meeting was called to order by the president, Dr. James Johnson, at 8:15 p. m.

There were forty-seven members and two guests present.

Minutes of the January meeting were read and approved.

Upon ballot the following men were elected as candidates for active membership in the Academy:

Dr. Philip Donohue and Dr. John Holt of Saint Paul, and Dr. William A. Hanson and Dr. O. S. Wyatt, of Minneapolis.

The scientific program followed.

DR. S. E. SWEITZER, Minneapolis, showed a general group of colored kodachrome pictures of skin diseases.

Discussion

DR. H. E. MICHELSON, Minneapolis: It is very difficult to discuss a presentation like Dr. Sweitzer's. We are only able to comment that his slides are very instructive, and that this Will Rogers of medicine has furnished us with much amusement. However, in spite of his facetious remarks, the work represented in this collection is great, and I am sure that as time goes on his collection will become more and more valuable.

LIP AND PALATE OPERATIONS

(Movies in color)

HARRY P. RITCHIE, M.D.

Saint Paul

Dr. Ritchie discussed some of the problems of repair of the congenital clefts of the face and jaw, showing movies in color of operations for several combinations of clefts of the lip, hard palate and soft palate. The main point of this presentation was that the principal thing in any given case, as they came in one after the other, is not the condition of the lip or the palate, but the condition of the alveolar process, whether it is normal or whether it is cleft. This fact has already been indirectly indicated since the beginning of the literature by the terms, "complete and incomplete cleft palate."

Through the interest and direction of Drs. Scammon, Boyden and Jackson of the Department of Anatomy and Embryology of the University of Minnesota, Dr. Ritchie has been able to demonstrate that, from an embryological viewpoint, the process is not a part of the palate but, on the other hand, is formed in relation to the lip. He pointed out that the only cleft requiring early treatment is the cleft in the process, because this cleft is in the bone, and it must receive attention as early as possible while the bone is soft and pliable. If the case with the cleft in the process is allowed to

go beyond the three-month period, the bones become set in their cleft position and it becomes increasingly difficult to contact the edges. For several years, in the treatment of alveolar process clefts, Dr. Ritchie used the wires and plates suggested by Dr. Brophy, thus applying direct force to the bone. He has now completely and irrevocably discontinued such procedures, because there is no way of determining the amount of force applied to the individual case, with the result that the upper jaw is malformed, with malocclusion with the lower jaw on one side or the other. This produces a surgical deformity which sometimes seems worse than the congenital deformity. To substitute the plan, Dr. Ritchie now tries to get all the cases with alveolar process clefts as early as possible and he applies indirect force by means of adhesive straps and rubber bands, gradually narrowing the cleft in the process by indirect force, with most satisfactory results. So soon as the process cleft can be narrowed down 4 to 6 m.m. in width, the lip is done over the process cleft to complete the closure.

Another advance in recent years has been the operation in which the front part of the hard palate is closed at the same time as the lip. This can only be done to the extent of two or three stitches but it does facilitate the subsequent repair of the hard and soft palates, which is usually done some time in the second year.

The lip operation was shown as performed in two ways: first, by electrical stimulation of the muscle bundles of the orbicularis oris, puckering these up to find the lower bundles at the vermilion border and the upper bundles at the base of the ala. These were then sutured together, supplemented by a third stitch between the upper and lower stitches, thus burying the stitches in the body of the lip, and tying them on the mucous membrane side. The same operation was then done by the use of calipers, taking as a starting point an obtuse angle which always is present in unilateral clefts, this point being the natural union of the prolabium of the fronto-nasal process and the maxillary process, right or left, to which it is normally united. Dr. Ritchie believes that the lip can be done without either electrical stimulation or calipers, because he believes that the position of the muscle bundles is always indicated by markings on the skin of the lip.

The bilateral cleft of the lip was shown in which one side is done at one sitting, making an effort to bring the muscle bundles of the lateral maxillary process to the midline of the prolabium, in which there is no muscle tissue. Then, at a period of six weeks to two months, the other side is done, making an effort to bring the muscle bundles of that side to the midline of the prolabium. Both sides of the bilateral lip being done at one sitting has now been discarded, because of the great precision and the time of operation required

to make proper contact. The prolabium of the fronto-nasal process is then placed in the body of the lip. This is a point of procedure upon which there is still no agreement. In support of the plan, Dr. Ritchie presented a case of cleft lip in which everything had completely united except a few muscle bundles on the left side which had failed to contact, being attached only to the skin margins and causing a line of depression in the skin, just the markings of the normal line of union. The outlines of the prolabium in this case were very evident and showed that it was a part of the normal lip and that the vermilion border of the prolabium was a part of the vermilion border of the normal lip.

Discussion

DR. ARNOLD SCHWYZER, Saint Paul: I don't know that I feel prepared to discuss these beautiful pictures except that I want to congratulate Dr. Ritchie on having made and shown them. This is a very special field and it takes a special dexterity to do these things. Dr. Ritchie several times has shown, when I saw him work, an extraordinary dexterity. I cannot help saying, though, that it is a little difficult always to see well when you have moving pictures in surgery. These are probably as good as any I have seen. Evidently the big field for colored pictures is dermatology, for they must be wonderful for teaching purposes.

The meeting adjourned.

A. G. SCHULZE, M.D., *Secretary*.

WOMEN'S AUXILIARY

MRS. A. C. BAKER, Fergus Falls, *President*

MRS. E. V. GOLTZ, 2259 Summit Avenue,
Saint Paul, *Publicity Chairman*

At the regular meeting of the *Washington County* Auxiliary held at the home of Mrs. E. Sydney Boleyn, plans were made for the completion of a poster showing the progress of the auxiliary during the year. This poster will be sent to the state meeting which will be held in Rochester, Minnesota, in April.

Park Region Auxiliary and Medical Society held a joint meeting in Fergus Falls at the State hospital, Wednesday, February 14. About seventy-five attended the dinner, after which members of the Auxiliary adjourned to the home of Dr. and Mrs. W. L. Patterson for their business session. The annual meeting of the Auxiliary will be held in April, when a new president will be elected.

The *Renville County* Auxiliary met for their February session with the following members attending: Mrs. R. Madland and Mrs. C. Hartman of Fairfax, Mrs. J. Dordahl of Sacred Heart, Mrs. R. Adams of Bird Island, Mrs. G. H. Mesker, Mrs. A. A. Passer and Mrs. J. A. Cosgriff of Renville. A book review was given by Mrs. Dordahl of Sacred Heart.

Mrs. D. G. Mahle of Plainview, Minnesota, was elected president of the *Wabasha County* Medical Auxiliary at the annual meeting held at the home of Mrs. C. G. Ochser. Mrs. Mahle succeeds Mrs. B. A. Flesche of Lake City. The newly elected vice president is Mrs. B. J. Bouquet of Wabasha and the new secretary and treasurer is Mrs. M. J. Campion of Lake City. Mrs. Race of Plainview was named scrapbook chairman. Following the election a luncheon was served.

The *Winona County* Auxiliary will send their newly elected president to the annual state meeting to be held in Rochester in April. This Auxiliary will hold their annual meeting in April. A recent meeting was called by the President, Mrs. H. W. Satterlee of Lewiston, and was followed by a luncheon held at the Garden Gate and attended by sixteen members.

The *Winona* Auxiliary has contributed this year to the school milk fund and to the purchase of *Hygeia*, which was donated to three Winona high schools and the high schools of Rollingstone, Lewiston and St. Charles. The Auxiliary has been very active this year in the Cancer Campaign.

Have you made your hotel reservation for the 18th Annual Convention of the Woman's Auxiliary to the American Medical Association, which will be held in New York City, June 10 to 14, 1940? Headquarters are at the Hotel Pennsylvania and we are sure you will not want to miss this convention, which promises to be an outstanding one. *Mail Your Reservation Today* to Dr. Peter Irving, Housing Bureau, Room 1036, 233 Broadway, New York City.

* * *

The *Hennepin County* Auxiliary held its last regular meeting March 1, when the group entertained members of other Auxiliaries of the state. A talk on "Spring Gardens" by Mr. Rodney Kelley was given with illustrated moving pictures.

The annual Easter Monday card party will be held on March 25. Money from this is used for philanthropic needs with the larger part of the money raised used for the personal needs of the extuberculosis patients who are living at Sarahurst—the boarding home supported by the Christmas Seal Sale. Contributions are made each year to the upkeep of "our room" which houses three girls. The parties each year are held in private homes as well as in the Medical Library. The following members will open their homes: Mmes. E. D. Anderson, E. W. Bedford, E. G. Benjamin, James Blake, L. R. Boies, A. E. Cardle, J. B. Carey, R. R. Craumer, C. D. Creevy, Peter E. Peterson, E. T. Evans, G. M. Hall, W. K. Haven, E. C. Henrikson, R. T. LaVake, C. O. Maland, Russell Morse, J. A. Myers, E. G. Oppen. The general chairman for these parties is Mrs. L. S. Arling.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

NEWER NUTRITION IN PEDIATRIC PRACTICE. I. Newton Kugelmass, B.S., M.A., M.D., Ph.D., Sc.D. Attending Pediatrician, Broad St. Hospital and Heckscher Institute, New York; Consulting Pediatrician Lynn Memorial Hospital, Monmouth Memorial Hospital and Muhlenberg Hospital, New Jersey, etc. 1155 pages. Illus. Price, cloth, \$10.00. Philadelphia: J. B. Lippincott Co., 1940.

THE MANAGEMENT OF OBSTETRIC DIFFICULTIES. Paul Titus, M.D. Obstetrician and Gynecologist to St. Margaret Memorial Hospital, Pittsburgh; Consulting Obstetrician and Gynecologist, Pittsburgh City Homes and Hospital, Mayview, and to Homestead Hospital, Homestead, Pa. Secretary, American Board of Obstetrics and Gynecology. 968 pages. Illus. Price, cloth, \$10.00. St. Louis: C. V. Mosby Co., 1940.

TEN YEARS IN THE CONGO. W. E. Davis, M.D. 301 pages. Price, cloth, \$2.50. New York: Reynal & Hitchcock, 1940.

HEIL HUNGER! Health under Hitler. Dr. Martin Gumpert. Translated from the German by Maurice Samuel. 129 pages. Price, cloth, \$1.75. New York: Alliance Book Corporation, 1940.

NON-PROFIT HOSPITAL SERVICE PLANS. C. Rufus Rorem, Ph.D., C.P.A. Director, Commission on Hospital Service, American Hospital Assn., Chicago. 130 pages. Price, paper cover, single copies 50c each; lots of 4 to 10, 25c each; 11 or more, 15c each. Chicago: Commission on Hospital Service, 1940.

SHOCK—Blood Studies as a Guide to Therapy. John Scudder, M.D., Med. Sc.D., F.A.C.S. From the Surgical Pathology Laboratory of the College of Physicians and Surgeons, Columbia University, and Department of Surgery, Presbyterian Hospital, New York City. 315 pages. Illus. Price, cloth, \$5.50. Philadelphia: J. B. Lippincott Co., 1940.

PNEUMOCONIOSIS—The Story of Dusty Lungs. A Preliminary Report. Lewis Gregory Cole, M.D., Director of Silicotic Research, John B. Pierce Foundation, New York, and William Gregory Cole, M.D. 100 pages. Illus. Price, cloth, \$1.00. New York: John B. Pierce Foundation, 1940.

PRECLINICAL MEDICINE. Malford W. Thewlis, M.D., Attending Specialist, General Medicine, United States Public Health Hospitals, New York City; Special Consultant, Rhode Island Department of Health; Associate Editor, Medical Times (New York), etc. 223 pages. Illus. Price, cloth, \$3.00. Baltimore: Williams & Wilkins Co., 1940.

GOOD HEALTH AND BAD MEDICINE. A Family Medical Guide. Harold Aaron, M.D., Medical Consultant to

Consumers Union of United States, Inc. 328 pages. Price, cloth, \$3.00. New York: Robert M. McBride & Co., 1940.

PHYSICAL DIAGNOSIS (Elmer and Rose). Eighth Edition. Revised by Harry Walker, M.D., F.A.C.P. Associate Professor of Medicine, Medical College of Virginia, Richmond, Va. 792 pages. Illus. Price, cloth, \$8.75. St. Louis: C. V. Mosby Co., 1940.

ESSENTIALS OF THE DIAGNOSTIC EXAMINATION. John B. Youmans, B.A., M.S., M.D. Associate Professor of Medicine and Director of Postgraduate Instruction, Vanderbilt University Medical School. 417 pages. Illus. Price, cloth, \$3.00. New York: The Commonwealth Fund, 1940.

DISEASES OF THE NOSE AND THROAT. Charles J. Imperatori, M.D., and Herman J. Burman, M.D. 2nd edition. 726 pages. Illus. Price, \$7.00. Philadelphia: J. B. Lippincott Company, 1939.

Though the first edition is only three years old, the authors have seen fit to issue a second edition of this work. This evidences a desire to keep the book abreast of recent advances in this field. Considerable new material is found in this second edition. Of this may be mentioned the newer knowledge of nasal allergy. The authors have also given attention to recent work on the physiology of the nose in bringing this section up to date. Acute laryngo-tracheo-bronchitis, a recently recognized entity, is discussed.

The same style and arrangement is followed which renders the material readily available. The paper and type are the best. The authors have followed their original plan of omitting controversial material and presenting salient facts and proven methods of therapy with little or no critical comment of other methods.

Though originally presented in the form of lectures for students, the book is a handy reference work for the practicing rhinologist and laryngologist.—A.G.A.

PSYCHOBIOLOGY AND PSYCHIATRY. A Text-book of Normal and Abnormal Human Behavior. Wendell Muncie, M.D., Associate Professor of Psychiatry, Johns Hopkins University; Assistant Psychiatrist, Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital. Pp. 729. Illus. 69. Price \$8.00. St. Louis: C. V. Mosby Company.

The author is a member of the staff of the Henry Phipps Psychiatric Clinic, Johns Hopkins Hospital. Dr. Adolph Meyer, Director of the Clinic, introduces the book with a foreword; he commends the author of the text because "he would also formulate best what he actually finds in his patients and uses in his teaching and in the service of therapy." In view of the fact that many workers in the field of psychiatry have for

Write for literature.

Chemists to the Medical Profession

THE ZEMMER COMPANY
Oakland Station, PITTSBURGH, PA.

MIN 4-40

MINNESOTA MEDICINE

some years past anticipated a textbook exposition by the eminent Director of the Clinic, the following excerpt in the Preface by Muncie is of interest: "This book . . . attempts to give a fair account of the conceptions, teaching and working methods of the Clinic as currently constituted." The text is aimed primarily for the use of students.

Contents are divided into four parts. In the first chapter of Part I the Historical and Philosophical Bases of Psychobiology are outlined. The other three chapters, comprising a total of 92 pages, deal with the Student's Personality Study. Then follow nine chapters in Part II devoted to Pathology and Psychiatry. Part III concerns Treatment and Part IV is given over to Historical Survey in Bibliography of the Development of the Concepts underlying the Principal Reaction Sets. This last part comprises 182 pages, almost a fourth of the text, a rather liberal space allotment it would seem.

The textbook contains 69 illustrations and an ample index; it deserves recognition as a valuable addition to American psychiatric literature.

J. C. MICHAEL, M.D.

POPULATION, RACE, AND EUGENICS. Morris Siegel, M.D. Published by the author, 546 Barton Street, Hamilton, Ontario, 1939. 206 pages. Price \$3.00.

This book is of interest to laymen and the profession alike, although medical men may question some of the statements made. For instance, epilepsy, in the light of recent advances in this field, is hardly a good

reason for sterilization. The classification of feeble-mindedness is arbitrarily based on the I.Q., which, taken alone, is a doubtful criterion. The number of mentally deranged in this country as given seems to be too high.

More in conformity with the opinion of the best authorities is the chapter on Race. The theory of Nordic superiority based on the pseudo-scientific works of Gobineau and Houston Chamberlain, is refuted. There is no pure race. The cultural heritage of the present day dates back to the Greeks and Romans, and certainly not to the wild nordic tribes. In the Middle Ages, the cultural advances were due to the Moors and Arabs, while the Renaissance was born in the Mediterranean countries.

With regard to population, the author calls attention to the fact that, while the birth rate in this country, as elsewhere, is falling, it is solely at the expense of the cultured urban population. The reproduction in the agricultural regions and among the poor and uneducated in the cities is abnormally high. Since mental derangement and criminality are both affected by environmental factors, it follows that the nation, while being depopulated, becomes tainted at the same time with unfit. Sterilization alone cannot cope with the situation.

Hence, the author advocates restricted marriage, segregation of the unfit during the entire reproductive period for women, and, above all, social reforms such as abolition of slums, broad education for the masses, and other measures of equal importance.

M. L. ZLATORSKI, M.D.

SILVER PICRATE

Wyeth

HAS SHOWN A CONVINCING RECORD* OF
EFFECTIVENESS IN ACUTE ANTERIOR URETHRITIS

due to *Neisseria gonorrhoeae* • *Trichomonas vaginalis*
Monilia albicans

Silver Picrate is a crystalline compound of silver in definite chemical combination with picric acid. Dosage form for use in anterior urethritis: Wyeth's Silver Picrate Crystals in an aqueous solution of 0.5 percent.

Supplied at all pharmacies in vials of 2 grams

Complete literature on Silver Picrate as used in genitourinary and gynecological practice will be mailed on request.

GASTROSCOPIC OBSERVATIONS IN PERNICIOUS ANEMIA*

J. B. CAREY, M.D.

Assistant Clinical Professor of Medicine
The Medical School, University of Minnesota
Minneapolis, Minnesota

THE flexible gastroscope (Schindler) offers an additional means of examination of the gastric mucosa in pernicious anemia. Early histologic studies of the postmortem gastric mucosa have long since established the fact that gastritis with atrophy is the constant finding. The very earliest examinations, of Hunter and others, were open to the objection that postmortem changes were not inhibited, but when Faber¹ and Bloch (1898) adopted the suggestion of Damaschino (1880) and Chauffard (1882) of formalizing the stomach and peritoneal cavities immediately after death, thus fixing the delicate tissues before change could occur, these objections were no longer valid. Meulengracht³ has more recently substantiated these findings, again on postmortem material.

Studies on functional activity have been made, particularly with respect to the inability of the atrophic mucosa in pernicious anemia patients to form hydrochloric acid. Since the use of histamine as a stimulant, this work has become standardized and tends to show that achlorhydria is a constant finding, not favorably influenced by therapy. Castle and others, following up the hypothesis that there is an intrinsic element of, or elaborated by, the gastric mucosa, necessarily present as a component of the complex of factors protective against the occurrence of pernicious anemia, have demonstrated that such a factor does not return to the organism in response to liver therapy. The relationship of this factor to the achlorhydria or the atrophic condition of

the mucosa is as yet not clearly defined. Meulengracht³ and Morrison⁴ have advanced theories, yet awaiting final proof.

By this time many cases of pernicious anemia have been examined gastroscopically, and the presence, always, of an atrophy of greater or less degree has been noted. Whether this condition is amenable to change by adequate liver therapy has been discussed, and favorable and unfavorable results have been recorded. The earliest report was that of Benedict et al² in 1935, but the cases upon which they based their conclusions were, perhaps, not just the sort of cases in which such conclusions would be warranted. Of five patients reported, three had polypi and two had carcinoma of the stomach. Two of those with polypi as well as the two with carcinoma were operated upon. Two of these operations were done before gastroscopic observations were made, and there is nothing in the record to show what therapy, if any, was instituted after operation. Bleeding was undoubtedly a factor in most of the cases. The association of polypi with atrophic gastric mucosa and anemia, or the association of carcinoma with a macrocytic type of anemia and atrophy of the gastric mucosa is not uncommon.

Schindler⁵ has more recently reported that he has seen the return to a normal condition of the gastric mucosa of some pernicious anemia patients who had shown atrophy of mucosa on original examination, following adequate liver therapy. His report includes four patients with pernicious anemia in whom he saw normal mucosa after treatment, although he had not examined them before treatment, and three patients observed before and after treatment, in one of whom

*From the Gastroscopy Clinic, Dispensary, Medical School, University of Minnesota, and the Medical Division, The Nicollet Clinic, Minneapolis, Minnesota. Read before the Minnesota Society of Internal Medicine, November 28, 1939, St. Paul, Minnesota.

the mucosa became normal, the other two still showing some atrophy, although not as extensive as at the original examination.

I have so far (750 examinations) not seen an indubitable case of pernicious anemia with a normal gastric mucosa. Moreover, I have not seen restoration to normal condition of gastric mucosa occur in any of the cases reexamined after treatment, although in some cases some evidence of regeneration was present. Fifteen patients who had been diagnosed unmistakably pernicious anemia by all the usual and accepted criteria were chosen. Six reexamined showed still very definite atrophic mucosa, although in two there was some improvement in that what were thought to be areas of regeneration were present. One was definitely worse, *i.e.*, the atrophy was more extensive. One had had inadequate treatment. One of the fifteen was examined for the first time when her blood was normal, having received liver extract for four years, but who had persistent gastric complaints; an actively inflammatory atrophic condition was seen. One of the fifteen had died, from what cause I do not know. Five of the fifteen did not respond to our request that they return for reexamination, and two of the fifteen who did come in could not be reexamined because of acute upper respiratory infection and have not been seen since. Another patient with marked mental changes was not reexamined and in another, because of complication of paralysis agitans, the examination was too difficult the first time to warrant repetition.

SUMMARY OF CASES

Number examined.....	15
Number re-examined.....	6
Worse—1	
Improved—2	
Unchanged—3	
Dead	1
Failed to return.....	5
Reexamination impossible.....	3

Case 1.—2-24-37 Atrophy. Hemoglobin 38, red blood cells 1,700,000. 7-7-37 no change. Hemoglobin 82, red blood cells 4,880,000. Therapy adequate.

Case 2.—3-3-37 Atrophy. Hemoglobin 56, red blood cells 2,480,000. 5-10-39 atrophy, slight effort of regeneration. Hemoglobin 88. Therapy adequate.

Case 3.—5-4-38 Atrophy. Hemoglobin 83, red blood cells 3,700,000. 6-15-39 no change. 5-27-38 hemoglobin 77, red blood cells 7,960,000. Therapy adequate.

Case 4.—1-18-36 Atrophy. Hemoglobin 52, red blood cells 2,980,000. 6-22-39 atrophy more marked. Hemo-

globin 97. Therapy probably not quite adequate in this case, as general condition was not very good.

Case 5.—5-1-36 Atrophy. Hemoglobin 70, red blood cells 3,860,000. 4-26-39 no change. Hemoglobin 64, red blood cells 3,080,000. Still some symptoms. Inadequate therapy.

Case 6.—2-3-37 Atrophy. Hemoglobin 53, red blood cells 2,260,000. 4-5-39 atrophy and areas of superficial gastritis. Hemoglobin 85, red blood cells 4,760,000. Considered adequately controlled.

Case 7.—9-14-38 Atrophy with inflammatory change. Hemoglobin 93. Not examined again. Patient considered to have been adequately controlled for four years.

Case 8.—4-13-38 Diffuse atrophy. Single polyp of anterior wall of stomach. Not reexamined because of paralysis agitans and diabetes.

Case 9.—9-21-38 Diffuse atrophy. Hemoglobin 50. 9-14-38 hemoglobin 35, red blood cells 2,040,000. Has had some liver but obviously inadequate amount.

Case 10.—5-27-36 Atrophy. Hemoglobin 42, red blood cells 2,350,000. Untreated. Patient died in 1938. Cause unknown.

Case 11.—11-4-36 Atrophy. Hemoglobin 76, red blood cells 3,220,000. Untreated.

Case 12.—11-25-36 Atrophy. Hemoglobin 41, red blood cells 1,900,000. Untreated.

Case 13.—12-2-36 Atrophy. Hemoglobin 40, red blood cells 1,500,000. Untreated. Returned 1939 but could not be reexamined because of acute upper respiratory infection.

Case 14.—2-3-27 Atrophy. Hemoglobin 38, red blood cells 1,180,000. Untreated.

Case 15.—2-7-37 Atrophy. Hemoglobin 54, red blood cells 1,680,000. Untreated. Not reexamined 1939 because of marked mental changes and lack of cooperation consequent thereon.

The reversion to a normal condition of the gastric mucosa in pernicious anemia patients treated with liver would be contrary to the pathologic and histologic studies of Meulengracht³ and Faber.¹ Both of these authors have examined post-mortem material from pernicious anemia patients adequately controlled as to anemia and dying from intercurrent causes, and have always found an atrophic condition of the mucosa with gastritis. Changed conditions of general nutrition and blood elements brought about by liver therapy in pernicious anemia might conceivably result in some improvement in gross appearance of gastric mucosa, as to color and even in the direction of recession of atrophic appearance. But, in any condition of gastritis, the replacement of diseased gastric cells is by non-specific, simple, columnar epithelium and not by functional cells capable of secreting any of the supposed specific substances; and at times the regenerated mucosa has the characteristics of intestinal mucosa. This

is also in line with the other experimental evidence, namely, the hydrochloric acid does not return to the gastric secretion in pernicious anemia in spontaneous or induced remission, nor does the so-called intrinsic factor. Once an atrophic condition of the tongue has been established, a restitution to normal appearance does not occur during either spontaneous or induced remission. If liver therapy actually restored the gastric mucosa to normal and if the gastric mucosal cells thus regenerated were capable of acting as the normal glands should, then, not only hydrochloric acid, but also intrinsic factor should return to the economy of the organism, and the blood could be maintained in a normal condition without the further aid of liver—in other words the patient would be actually cured of his pernicious anemia.

This happy result has, so far, not been accomplished. Therefore, even if there is an apparent improvement in the atrophic condition of the gastric mucosa as seen gastroscopically in pernicious anemia patients as the result of liver therapy, such improvement would probably be because of replacement of atrophied mucosal elements by other new epithelium, probably of simple columnar type, sufficient to cover over the submucosa, hide the blood vessels and give the appearance of a normal gastric mucosa. Based upon the healing effects seen in other conditions, it is not likely that these replacement cells would be capable of performing the specific functions of the original, normal mucosa, and hence the lack of intrinsic factor, hydrochloric acid and other perhaps now unknown effective elements for anti-pernicious

anemia influence would still be lacking. The patient would still have pernicious anemia.

Until satisfactory histologic studies of the gastric mucosa of patients well controlled as to the pernicious anemia state, dying of some unrelated circumstance, have been made, conclusions based upon observations of gross conditions observed gastroscopically may not safely be extended beyond the point of description.

Supplementing the body's economy with what seems to be obviously lacking, seems to arrest the progress of the disease and to restore to apparent normal the hemologic elements; but the disease itself persists. As soon as liver is withdrawn from any individual, he more or less promptly relapses; the fundamental factors have been prevented from operating, but their existence has not been abolished. The gastric mucosa may be, by improving the blood and general nutrition of the pernicious anemia patient, apparently or actually regenerated, by some sort of reparative cells, from its atrophic state, but it is unlikely that the disease "pernicious anemia" is thereby permanently influenced.

A PROPER AND ADEQUATE PROTEIN DIET FOR ELDERLY PEOPLE*

E. L. TUOHY, M.D., F.A.C.P.

Duluth, Minnesota

WE ARE becoming a nation of elderly people. This is modifying our practice to a degree that few appreciate. I ask a lenient attitude on your part and the privilege to indulge in some repetition. A year ago I spoke before this Society concerning the overriding of food and vitamin deficiencies, and reported upon the therapeutic potentialities of thiamin chloride. I demonstrated an instance of extreme gastric

atony and stasis in a man with tabes and diabetes where parenteral thiamin chloride promptly restored gastric tonus and emptying time. I have since encountered an extreme megacolon in an instance of alcoholic polyneuritis. This colon came back to normal size and function, but only after much more prolonged restoration of adequate diet and with thiamin chloride fortification. This type of atony is comparable to that occurring to the heart in beri-beri.

Many articles dealing with vitamins and nu-

*From The Duluth Clinic, Duluth, Minnesota. Delivered in part before the Minnesota Society of Internal Medicine, Saint Paul, Minnesota, November 27, 1939.

trition continue to appear. Vitamin concentrate manufacturers continue their vivid and eager display through every advertising medium. The good, the dubious, and the bad get equal emphasis. We are, indeed, in the midst of much propaganda but it must be granted whereas it is usually an evil agent, there must be something said for publicizing certain principles that, like "faith, hope, and charity," are inherently good. So it is with the material food supplies which provide human sustenance. Indeed, it is to secure an abundance thereof that we see developed the most debasing and disastrous of all propaganda—both economic and military. It is timely, therefore, not only to attempt to keep step in utilizing the specific products (vitamin concentrates and synthetics) but to scan the broader generalities uncovered by studies in food deficiencies that we may more sensibly adjudge man's needs at various ages or in certain environments. This simply means an attempt to outline for humans a "balanced ration" comparable to that which agronomists and schools of agriculture have effectively and scientifically devised for domestic animals.

Since the very expression "domestic animals" connotes their utilization for burdensome work and as sources of human food it should be unnecessary to reiterate that man came out of caves and developed modern contrasting rural and urban living, through animal husbandry. Considering the long mutual interdependence existing between man and domestic animals—horses, hogs, goats, cattle, sheep, and chickens—I wish to stress only the enormous contribution of animals to man through acting as concentrators of forage and materials too unwieldy for him to utilize. The almost overwhelming corn crop of our Middle West is marketed neither in sacks nor in jugs although garden portions reach our tables or our bars in those forms. The great bulk of our corn is sold in the form of beef and pork products. They are the best in the world. We should not render them suspect on a series of false assumptions of inherent dangers arising from protein intakes that are reasonable, not to say adequate. This seems obvious. Few of us, however, are free of dietary prejudice; and for the elderly especially (and some of the reasons I shall present) the idea is deep seated—"You dig your grave with your teeth"—therefore eat little of that for the mastication of which they were ideally devised.

Primitive peoples of all periods have attacked and dispatched flesh food with gusto whenever they found it. African elephant hunters describe the same sort of feasts that Stefansson encountered among the seal-eating Esquimaux. (Recall also the relish they have for the raw viscera with their vitamin stores.) Somewhere, however, within the maze of medieval contrasts between gluttony and asceticism there arose antagonism toward the flesh meat. Religions, both Oriental and Occidental, found outlets for hygienic and spiritual guidance in restrictions, limitations and fastings in which the "flesh pots" attained conspicuous condemnation. The cost of meat and the difficulty of its preservation entered in and helped engender the class struggles still so much a part of life. I wish to make it clear that these esthetic, economic and traditional factors affect the older age groups in much greater proportion than the young.

So much has been published about life expectancy extension along national lines, it occurs to me that local statistics bring the situation much closer to our consciousness. To accomplish that purpose I submit some statistics recently compiled by Duluth's Health Commissioner.* They tell their own story. While the very great saving of infants under one year is admittedly the greatest source of life extension, still the gains after forty-five and the survivals after seventy-five are striking. No one should be surprised by the accumulating interest in Townsend Clubs and adventures in security.

TABLE I. AGE AT DEATH STATISTICS
(Duluth, Minnesota)

	1900	1937
Average age at death (arithmetical)	26.79	58.65
Deaths at age—under 1 year	24%	5%
over 75 years	4%	25%
Those attaining 45 years or more	24%	79%

The much publicized increase in life expectancy in the United States from 1901 to 1936 is featured in Table II.

A balanced diet for normal individuals is surely comparable, in promoting efficiency, to that of "a sane mind in a sound body." Most people do not need to be urged to eat. We may indeed have an excess of Sancho Panzas with us. Suit-

*I am indebted to Health Commissioner Dr. Mario Fischer for these Duluth figures and statistics.

TABLE II. INCREASE I— LIFE EXPECTANCY*
(1901 to 1936)

Year	Expectancy at Birth Years
1936	60.81
1935	61.37
1934	60.79
1933	61.26
1932	61.07
1931	60.26
1929-1931	59.57
1919-1920	56.42
1910	51.49
1901	49.24

able nutritive elements for the human gastrointestinal system are as important as a properly adjusted octane content gasoline is for a motor and its carburetor. When special emphasis is placed upon protein it is not an assumption that other necessary food elements are to be despised. This statement stems from the tendency of many people to develop their food habits with not only religious tradition but fervor as well. In other words, it is a highly personal matter conditioned by all sorts of circumstances including fads, fashions, and hunches, based on suppositions, someone's say-so, or confusions engendered by familial, social, environmental and personality quirks. The prejudice against protein has been considerable. As people grow older, age and the battle of life bequeath body squeaks, even as they come to used cars. To these weaknesses of the flesh is all too often added economic dependence. The obsolescence of skills and employment are the unhappy by-products of attempts at security which stand in the way of continued employment for the old. Consorts die and previously self-sufficient contented households are broken up. The "bachelor scurvy" so vividly described by Castle arises from the lack of incentive to prepare food for those eating alone or from fantastic choosing on the part of widowers, for example, long accustomed to conscientious safeguarding by their consorts. It is in this inelastic period of life people are prone to dump the blame upon something they ate. The salutation, "How's your liver?" of older times (likely an outgrowth of the era of humors) expressed a fundamental and physiologically sound approach to a good health appraisal.

Therefore, I turn to current research on liver function to help establish the principle of a higher protein bodily need than is usually considered.

The epochal work of Mann and Bollman and their co-workers on the protective values of foodstuffs in the matter of limiting hepatic lipid has focused our attention upon carbohydrates to sustain and prolong life in the presence of a severely damaged liver. This teaching has greatly influenced surgical and medical therapeutics. At the same time it is possible that it has more or less submerged the equally obvious circumstance that protein protects the normal liver. Time does not permit going into this in further detail except to point out the excellent experimental work with chloroform inhalation on animals made by Goldschmidt, Vars and Ravdin.⁴ These observers agreed with Mann and Bollman in according protective value to those foodstuffs which limit the deposit of liver fat. They point out that it is not true that protein is all immediately utilized unless fixed in living tissue. They give argument substantiating some degree of protein liver storage. They state that some of the carbohydrate protection afforded the liver comes indirectly through sparing protein for its more vital purpose. The essential point involved seems to be that protein is needed for the building of new body tissue, regardless of how the protein is spared or utilized. The basic need of protein is admitted. It is largely a question of how much.

The damage to hepatic cells after one hour's chloroform anesthesia increases progressively and decisively as lipid concentration in the liver increases. A high concentration of glycogen by itself did not seem to protect the liver of rats against the hepatotoxic action of chloroform. In general rats with high protein diet stood a lot more chloroform with less liver necrosis than those with depletion of protein stores after starvation. This is in a measure the story of alcohol and liver damage in the human.

The expression "living on the fat of the land" describes that finish and gloss (whether applied to man or beast) which properly acclaim and establishes the needful fat requirement. Burr² recently gave before the program at the University of Minnesota Fiftieth Anniversary Meeting a summary dealing especially with the highly essential fatty acids. On the same program Whip-

*Excerpted in part from Harwood, Murray P.: An Evaluation of the Factors for Public Health Progress in the United States. Science, 89:517, (June 9) 1939.

ple,⁸ of erythropoietic development fame, spoke upon the production, utilization, and significance of blood plasma. Not only did he mention the circumstance that the liver plays a very great part in the formation of plasma protein but pointed out that, in general, plant proteins are much less effective as a source than those coming from animal tissue. This introduces to us the whole subject of what is and what is not "proper and adequate protein" with the need of studies distinguishing the amino acids and attempting to allocate their distinctive properties and functions. McLester⁶ quotes from the Harvey lecture by Rose, "twenty-one known amino acids in purified form—yet one more, threonine, was indispensable for growth." The specific action of these proteins, simple or combined amino acid complexes, seem to trek hand in hand with certain of the vitamins and all are tied up with that intricate mechanism of tissue cell respiration for the elucidation of which Warburg over a decade ago received the Nobel prize.

The situations involved in the studies of energy release at the level of the cell membranes is abstruse but intriguing. This involves some very intricate biochemistry. Clinical physiologists (as attested by many articles) are currently striving to suggest its practical application. The subject was recently summarized editorially in the *Journal of the American Medical Association*.³ The circumstance which should challenge our attention (and urge continued attempts at understanding the chemical physical processes involved) arises from the readily understandable fact that (unlike energy release at very high temperature and pressure levels in a motor or furnace) living tissues must effect such release at relatively low temperatures. Active agents, the reverse of chlorophyll in plants, which link up radiant energy with water and carbon dioxide for plant growth (and in turn becomes the food for animal growth), must unloose this energy to living cells. Numerous catalysts further oxidation first by delivering hydrogen (dehydrogenation) to "acceptors"; to be followed by oxidation through a great variety of systems in which enzymes and co-enzymes promote the reaction. Up to date a great deal of theory intervenes but we know without any theory that inert proteins become living protoplasm and selective action by body cells occurs according to Whipple without the necessity of entirely breaking down protein mole-

cule aggregations into their component amino acids.*

Endocrine products (internal vitamins) may not be left out of this complicated set-up, as is well illustrated by the action of insulin on glucose. Tuttle⁷ has recently stated the probable mechanism of interaction of the pituitary and suprarenal through central nervous linkage with the blood stream demands, generated by tissue cell needs. The feature I return to is the circumstance that physiologists place the essential process of "phosphorylation" (break-down of the molecule to a size such that normal osmotic pressures suffice for capillary membrane permeability) chiefly in the liver. After insulin accomplishes this transfer of glucose to glycogen it has no further part in the metabolism of glucose. Arterial blood is said to contain no insulin. Its reaction, therefore, terminates at least with the entrance of blood into the left heart. Another biochemical observation bears upon phosphorylation and the liver. Spies states that the substance cocarboxylase (now synthesized) is as effective as thiamin chloride and is the latter substance after phosphorylation. He suggested its use in the circumstance where liver function is so far reduced that (comparable to the ineffectiveness of Vitamin K in marked liver function depression) thiamin would be inactive. No doubt as knowledge advances many of these conclusions may suffer adaptation, withdrawal or limitation. Nevertheless, at this time, liver assemblage, reconstruction and storage, may not be over-emphasized. Since the deposit of lipid in the liver is for the most part unfortuitous, and available glycogen is largely expedient for rapid and immediate energy release, then it follows that protein sufficiency is paramount. When we add to this the intricate and intimate specific manner in which certain amino acids are linked with enzymes, co-enzymes, endocrine products and vitamins, we begin to appreciate the early work of Goldberger, who pioneered with a diet rich in lean meat for pellagra, long before Elvehjem isolated nicotinic acid. The intimate association of these necessary stabilizing and protective substances with protein cannot be accidental.

It is possible to assemble a surfeit of clinical

*Biochemists link together cytochrome, Warburg's yellow respiratory ferment (containing riboflavin from B₂) and glutathione as active acceptors. Ascorbic acid⁵ and glutathione are ranked as the most active reducing substances in living tissue. The former is found most abundantly where cell activity is intense (suprarenal).

evidence that low protein diet where it has been the traditional rule is either valueless or (what is more likely) baneful. High protein diets are now recommended in acute nephritis (McKhann) where it is necessary to offset urinary protein loss; hypertension is in no way inhibited by leaving out meat and many subjected thereto become tired and anemic; arthritics (whatever the cause) need upbuilding and while gout may call for dietary direction, it is by no means controlled by fasting; much abuse exists in the treatment of peptic ulcer and so-called colitis by pap diets; obstetricians know that pregnant women (so commonly anemic) need forcing of a full diet even if exhibiting signs of toxemia; the condition described by Wills among women in India is practically the same as that described by Alsted¹ as extrinsic pernicious anemia and due to low protein in the diet; protein deficiencies in idiopathic hypochromic anemia are usual, secondary to the anorexia of achlorhydria—in fact a meat diet stimulates hydrochloric acid output. After all these are summarized, we return to the plight confronting those who are growing old, and if we observe carefully we find among them instances of malnutrition. When appetite recedes from any cause meat or its equivalent is usually the first item left out. This comes from necessity when economic reverses come; but to many the reversal is in the province of the mind. Physicians have all too long been guilty of blanket injunctions as nebulous as the miasmas—"cut down your eating"—"secure a bland diet"—"take nothing but white meat."

We know the chief issue behind the avitaminoses is proper food. Fortification with vitamin concentrates (Elvjhem) may be indicated in some soil-impooverished areas, but certainly not in our glorious midcontinental alluvial treasure land. It is far more than a medical problem to effect such distribution as common sense dictates must ultimately obtain. But we must now retract in terms of the convincing output of nutritional research, and gradually antidote, the damage we have previously done by suggesting low meat diets. As far as mental inhibitions are

concerned, it should be helpful to recall that researchers in nutrition unanimously report that the rat instinctively seeks and eats what he needs if he is able to get at it. Instinct is too often repellant to humans and their great gift of consciousness is diverted to the support of cultism, faddishness and mimicry. Women have long been accused of partiality toward this very human propensity. No man who ever takes the time to peruse our hospital diet lists or read a book replete with dietary outlines would ever recognize in his sex any notable insulation toward the same tendencies. Every folly ever embodied into routine textbook fill-ins that supposedly outline dietary regimen in various disease states continues the incubus with each revision or translation.

There will be a tendency on the part of a few to reject this thesis. Some will confuse the urge to eat normally with justification of gluttony. Others may confuse the issue of obesity or its associates, diabetes and arteriosclerosis (so fearsome to insurance actuaries). But we may add, where shall we turn unless to adequate protein, to keep down weight, avoid overtaxing carbohydrate tolerance (Joslin), or (if you think O'Leary's lead is right) postpone lipid arterial infiltration. Certainly as the years extend and senescence arrives, proper guidance includes accommodating effort to capacity. That, with explicit application of the principles I have outlined, is the chief concern and purpose of geriatrics.

While stomach lavage is not practical or even necessary for universal use, no patient with clinical signs of tuberculosis who has negative saliva should be considered negative for the disease until stomach lavage has yielded negative results. The absence of tubercle bacilli in only one stomach washing does not necessarily signify that the disease is arrested, especially when the collapsed lung is re-expanding. A. GENITAL TUBERCULOSIS*

GILBERT J. THOMAS, M.D. and T. L. STEBBINS, M.D.

Minneapolis, Minnesota

and

FRANK J. RIGOS, M.D.

Oak Terrace, Minnesota

PROGRESS in the early diagnosis and treatment of renal tuberculosis did not occur until urologists and phthisiologists, working together, began to study the disease—tuberculosis—which disclosed that lesions in the kidney are local manifestations of a generalized infection. During this study it became apparent that the route of spread of the infection from the chest cavity to other organs and tissues is lymphohematogenous. This means that all tissues or organs in the body may become infected with bacilli of tuberculosis when spread has occurred from the chest cavity. Local susceptibility, anatomical and developmental faults, the number of blood vessels in organs and tissues seem to be factors that determine which ones are most often infected.

A careful review of the literature and the data obtained from our clinical study of many patients reveals that the diagnosis and treatment of lesions of tuberculosis of the genital tract require the same understanding of the disease tuberculosis and the route of spread of infection as does tuberculosis of the kidney.

Route of Spread to the Genital Tract and the First Organs Involved

The route of invasion, the location of the first lesion, and the method of spread of bacilli of tuberculosis to and in the genital tract are etiological factors about which there is still no general agreement among urologists and phthisiologists. When evidence of spread from the chest cavity has occurred, we find that the kidneys will be involved in 4 per cent and the genital organs in .6 per cent.

How do bacilli of tuberculosis reach the organs and tissues in the genital tract? Some observers are quite sure that the only route of invasion is via the blood stream and that when this occurs the epididymi or the seminal vesicles are first involved. Others believe, including ourselves, that bacilli of tuberculosis present in the urine from a renal lesion may infect the prostate

gland via the mucosa of the posterior urethra and the prostatic ducts and from here spread to other genital organs. Some clinicians recognize the possibility of both routes of infection being operative when the genital organs are involved.

Moore,¹⁷ a pathologist from the New York Hospital, examined serial microscopic sections of certain areas of autopsy specimens of the prostate gland. Moore tried to determine the most frequent location of lesions of tuberculosis in the prostate gland and the anatomical relationship of the lesions to the duct openings, the blood vessels and the acini of the glands. Moore found the majority of microscopic lesions near the blood vessels, and at the periphery of the prostate gland, so that he states that the route of invasion is most often via the blood stream.

Data obtained during our clinical examinations of both normal and pathological tissues and organs removed by surgical operation or during autopsy do not agree with Moore's published opinions concerning the most frequent route of invasion of the prostate gland by bacilli of tuberculosis.

We are sure that an organ like the kidney or the prostate gland must be completely serially sectioned and all sections examined through the microscope before one can say that the organ does not contain a lesion of tuberculosis.

The statements made and the opinions expressed in this paper are based on: (1) the data obtained during repeated urological examinations and the clinical data in the records of many patients who had some lesion of genital tuberculosis and who were observed at Glen Lake Sanatorium; (2) the pathological study of tissues removed during surgical treatment and at autopsy; and (3) a study of the data obtained from the autopsy protocols of 17,777 consecutive autopsies done by members of the staff of the Department of Pathology of the University of Minnesota.

Glen Lake is a county tuberculosis sanatorium

*Thesis read before the Minnesota Academy of Medicine, November 8, 1939.

and has a bed capacity of about 700. All age groups and patients with all types of lesions of tuberculosis are admitted to this institution so that we have an opportunity to study and to observe the disease tuberculosis in all its forms.

The relationship of lesions that occur in the urogenital tract to other lesions of tuberculosis and methods of spread were studied in eighty-seven patients who had some lesion of genital tuberculosis and who could be followed for at least two years. Eighty-seven per cent of this group had demonstrable lesions of tuberculosis elsewhere, 78 per cent being in the lungs. Sixty-four of our cases were well enough so that they could be repeatedly examined over a period of at least two years. *Ninety-two per cent had evidence of a lesion or lesions of renal tuberculosis.* The diagnosis of the renal lesion was made following repeated guinea pig inoculations of the urine sediment obtained from both kidneys.

Thirty-eight of our cases were examined before we were aware that lesions of tuberculosis in the genital organs begin in the prostate gland and that they are secondary to hematogenous lesions in the kidney. Routine instrumental examinations of the prostatic urethra and the ducts of the prostate gland were not made at this time. Many of the patients in this group of cases had epididymectomies before coming to the sanatorium. Many had no urological examinations.

During the time that we have routinely examined the kidney for evidence of the primary urogenital lesion, and since we have searched for lesions in the prostate gland, we have not failed to find evidence of a tuberculous lesion in the prostate gland when other genital lesions are present.

The data obtained from examination of twenty-three autopsy specimens more accurately reveal the facts concerning the first lesion of tuberculosis in the genital tract. We found evidence of tuberculosis in every prostate gland removed from patients who had genital lesions of tuberculosis. The kidneys removed from these patients contained easily demonstrable lesions of tuberculosis in twenty-two instances.

When genital lesions of tuberculosis are found or are suspected, *the whole urogenital tract should be carefully examined.* Our routine urological examination for evidence of urogenital tuberculosis not only includes the examination of

the kidneys but the genital organs and tissues as well. The utriculus, prostatic urethra and ducts of the prostate gland are always carefully examined through the endoscope or cystoscope. We have found evidence of infection in the prostate gland, *i.e.*, large duct openings and cavities, when the patient had no urinary symptoms or clinical findings suggesting lesions in this anatomical area. We believe that the prostate gland can be infected without the infection spreading from this organ into the vas, epididymis, or the seminal vesicle. We have examined many patients in whom evidence of tuberculous infection of the prostate gland could be demonstrated when the palpating finger introduced into the rectum did not find irregularities, nodules or firmness. In some instances we have found the size and extent of lesions in the prostate gland to be out of all proportion to a small lesion that may be found in the kidney. Our clinical data, obtained during careful repeated urological examinations of many patients with lesions of urogenital tuberculosis, disclose that the prostate gland is the first organ of the genital tract invaded with bacilli of tuberculosis.

One of us (Stebbins)¹⁸ recently examined the autopsy protocols of 17,777 consecutive autopsies done by members of the Department of Pathology of the University of Minnesota. In this group Stebbins found 1,283 cases having some gross evidence of infection with the bacillus of tuberculosis. Two hundred of these cases had some lesions of urogenital tuberculosis. Forty-five had lesions in the prostate gland, forty in the urinary bladder, twenty-three in the testes, sixteen in the epididymi, and fourteen cases in the seminal vesicles. Stebbins found thirteen instances of associated lesions in the epididymi and the prostate gland, and only three cases of tuberculosis of the epididymis not associated with infection in the prostate gland. Only four of the fourteen cases of tuberculosis of the seminal vesicles had no gross evidence of lesions of tuberculosis in the prostate gland. Most of these diagnoses were made following inspection of the gross specimen; some by microscopic examination of tissue removed from suspicious areas. The data from the examinations here quoted might have been different had serial microscopic studies been made of the whole organ. We believe that if this could be done, all patients with lesions of genital tuberculosis would have

an active focus or at least some evidence of an old lesion in the prostate gland.

Fenwick,¹¹ who reported data from 157 autopsies, found 3 per cent of urogenital lesions of tuberculosis in the prostate gland alone, 24 per cent in the prostate gland and epididymis, 3 per cent in the prostate gland and vesicle alone, and 6 per cent in the prostate gland and bladder.

In 1903, Hanson¹² produced tuberculosis of the epididymis and the testicle of rabbits by injecting bacilli of tuberculosis into the vas deferens. He found tuberculosis of the bladder almost always associated with tuberculosis of the utericle and the prostate gland.

Barney and Cabot⁷ reported data from 101 cases of urogenital tuberculosis and found the prostate gland involved in 75 per cent.

Collinet⁹ found the kidneys and prostate gland the urogenital organs most often infected with bacilli of tuberculosis. These may be the only urogenital organs involved.

Howard Jeck¹⁴ of New York, reporting from the Bellevue Hospital, found genital lesions present in a large percentage of cases of renal tuberculosis. Jeck's opinion is that lesions of genital tuberculosis always suggest the presence of renal infection. The examination of the genital organs during four autopsies which Jeck made upon patients who had renal tuberculosis disclosed lesions in the prostate gland in three.

Menville and Priestly¹⁶ of the Mayo Clinic recently published the data obtained from their pathological study of prostate glands removed from patients who had died of some lesion of tuberculosis. The prostate gland was, because of its close proximity to the urinary tract, the first and most frequent genital organ involved. Early small lesions of tuberculosis were very hard to find in the prostate gland. By direct extension these may involve the epididymis or other genital organs. These writers report that the epididymis, the testicle and the seminal vesicle may, at times, be the primary seat of genital infection with the bacillus of tuberculosis. In their opinion these lesions are blood-borne although Menville has reported that lesions of renal tuberculosis were associated with genital lesions in 74.2 per cent of his cases that did not include miiliary infections.

Wells¹⁹ found tuberculosis of the epididymis invariably secondary to lesions of tuberculosis in the kidney. This writer did not mention the

prostate gland as probably the first genital organ involved.

Some writers have reported *primary lesions of tuberculosis* in the genital organs. We have never encountered one during many years of experience. Primary lesions of tuberculosis in the chest cavity may be minimal, may not produce local symptoms, and lesions that occur elsewhere following spread may be gross lesions which produce many symptoms. Lesions in the kidney that eventually produce metastatic lesions in the genital tract may be minimal ones. The bladder infection, if present, may produce no symptoms and cystoscopic examination may not reveal much evidence of a secondary cystitis, but the prostate gland may become infected and the epididymis may reveal evidence of secondary lesions.

Route and Method of Spread in the Genital Tract

We believe that the mucosa of the prostatic urethra, the ducts of the prostate gland and their openings, and the ejaculatory ducts and their openings may become infected with bacilli of tuberculosis that are present in the urine.

Spread may occur by direct extension along the mucosa of the ampulla into the seminal vesicle and along the vas into one or both epididymi. Clinical reports show that bilateral epididymitis occurs in 60 to 75 per cent. We believe that this large percentage of bilateral infection in the epididymis occurs because the utriculus may be frequently reinfected by chronic lesions in the substance of the prostate gland and its duct. Lesions in the seminal vesicle may occur with none (rarely) or only minimal lesions in the prostate gland.

Diagnosis of Lesions of Tuberculosis of the Genital Tract

The diagnosis of lesions of tuberculosis in the genital tract may be very difficult. Lesions may be present in the prostate gland and seminal vesicles without producing urinary or other symptoms noticeable to the patient. Rectal palpation may not reveal nodules, induration or infected areas. Acute lesions of tuberculosis of the seminal vesicles are reported. I cannot remember one such case in over eighteen years of study of urogenital tuberculosis. In association with tuberculosis of the prostate gland I find

tuberculosis of the seminal vessels occasionally but not as frequently as has been reported in the literature. It is difficult to make a positive diagnosis of tuberculosis of the seminal vesicles except when a firm indurated organ may be palpated and when the examination of the expressed secretion reveals bacilli of tuberculosis.

We frequently find evidence of tuberculous infection in the prostate gland with the cystoscope or urethroscope during routine examination of the whole urogenital tract. We may find large infected ducts of the prostate gland and small areas of necrosis surrounding the duct openings and in the substance of the gland from which pus exudes when pressure is made over this area. Nodules, irregularities, indurations and firmness found in the prostate gland with the palpating finger in a patient who has or who has had any lesion of tuberculosis, active or at the present time quiescent, should be considered a lesion or lesions of tuberculosis.

Tuberculous lesions in the epididymis produce swelling, tenderness, induration, irregularity in the contour of this organ and frequently a cord-like swelling and induration of the vas deferens. Subacute tuberculous inflammation may occur in the epididymis. This may be recognized clinically as a slightly swollen tender epididymis that is not nodular. Trauma frequently activates this subacute condition so that acute symptoms such as pain, swelling, high temperature and tenderness occur. This subacute condition in the epididymis is always associated with active infection in the prostate gland. This may be caused by the bacillus of tuberculosis or other bacteria and may go unnoticed if trauma had not been applied to the epididymis. Secondary infection may be present so that a differential diagnosis must be made. This is not difficult when any discharge from the urethra may be examined. If a lesion or lesions of tuberculosis are known to exist elsewhere in the body, the examiner must assume that those in the prostate gland and epididymis are tuberculous.

The first lesions of tuberculosis in the human body (except the bovine type, which is rapidly disappearing in this country) begin in the chest cavity, so that any lesions found elsewhere are metastatic ones and are evidence of a hematogenous spread from the chest cavity. However, lesions of tuberculosis in the epididymis are secondary to those in the prostate gland in

most instances, and the kidney contains the primary hematogenous lesion or lesions in the urogenital tract.

Treatment of Tuberculous Infection in the Genital Organs

Before treatment for lesions of tuberculosis in the genital tract is undertaken, the patient should be thoroughly examined for evidence of other lesions of active or quiescent tuberculosis. The urogenital tract should be thoroughly examined for evidence of lesions elsewhere in the genital tract and for the primary lesions in the kidneys. When the data obtained during these examinations are at hand the treatment of the genital lesions may be planned. When active lesions are found in the chest cavity or elsewhere, hygienic treatment only should be started. Most patients with any lesion of tuberculosis will gain if they are put at rest in bed. Heliotherapy may be used if this is indicated and if it is beneficial to the patient.

If a renal lesion is found this should receive appropriate treatment before treatment of the genital lesion is started. The surgical or other treatment of a renal lesion plus continued hygienic treatment after surgical operation will control and arrest lesions in the prostate gland.

Surgical extirpation of the prostate gland is never necessary.

Tuberculosis of the seminal vesicle will recover without surgical treatment if tuberculosis of the kidney is brought under control and hygienic treatment is practiced long enough. Lesions of tuberculosis in the epididymis should be treated actively, but surgical treatment is not always necessary. We have found continuous heat therapy locally, the surgical drainage of abscesses near the skin, and hygienic treatment satisfactory in most cases. The prolonged and continuous application of heat for long periods may be all the local treatment that is necessary. When other lesions of tuberculosis of the urogenital tract and elsewhere in the human body have been controlled and when local treatment of the epididymis has been unsuccessful, then we believe that surgical dissection and removal of the epididymis and the vas up to the internal ring should be practiced. We do not remove the testicle, and we are very careful to try to preserve the blood supply of this organ, although we are not always successful. The blood ves-

sels of the epididymis and the testicle anastomose freely. There are many different anatomical arrangements of the areas where anastomosis of these vessels occurs. When complete dissection and surgical removal of the epididymis and the vas is necessary, slough or atrophy of the testicle may occur, although careful protection of the vessels in the cord was practiced during surgical treatment. Inadvertently, the surgeon may remove all the blood vessels which supply the testicle when careful dissection is made and the epididymis is removed.

Following the surgical removal of the epididymis or any other organ containing a lesion of tuberculosis, the patient should remain in bed for at least three months at complete rest. This is advised so that active lesions which may have been undiscovered and others which may have been activated by the surgical trauma may again become inactive and quiescent.

Conclusions

1. Tuberculosis of the genital tract is a local manifestation of a general disease and lesions here are most often secondary to a primary urinary tract infection in the kidney. The treatment plan of the local genital lesion or lesions must be based on this pathological fact.

2. The route of spread from the kidney to the genital tract is most often via the urine.

3. The primary lesion in the genital tract is most often the prostate gland. From here the infection may spread to the other genital organs. Foci of tuberculosis in the prostate gland may produce no symptoms.

4. The seminal vesicle is infrequently infected with the bacilli of tuberculosis and is most always associated with lesions of tuberculosis in the prostate gland.

5. Tuberculosis infection in the epididymis is secondary in the genital tract to tuberculosis in the prostate gland. There may be a subacute stage of tuberculosis of the epididymis which is activated by trauma.

6. Treatment of lesions of tuberculosis in the genital tract consists of:

(a) The location and arrest of other lesions of tuberculosis and of the primary focus in the urinary tract by whatever means are necessary.

(b) Hygienic treatment of lesions of tuberculosis in the epididymis and heliotherapy to be followed by application of heat, incision and drainage, and surgical removal when indicated.

(c) Orchidectomy is rarely necessary.

(d) Hygienic treatment for tuberculosis of the prostate gland and seminal vesicles after removal or arrest of other active foci in the urogenital tract is always practiced. Surgical removal of these organs is seldom necessary.

(e) Postoperative rest for three months is always essential.

TUBERCULOSIS IN THE AGED

It is known that when old people are found to have tuberculosis it is almost impossible to teach them to take care of themselves and protect others from infection. They will not cover their mouths during a cough or sneeze, nor will they try to protect or destroy their sputum. Their idea is that they have lived all these years with this old cough, it will not hurt them and they do not see how they can hurt anyone else. Elderly people with a chronic cough and positive sputum are a menace to society and should be isolated. C. L. Harrell, M.D., *Virginia Med. Monthly*, November, 1939.

SURGICAL DRAINAGE OF THE ABDOMEN*

A Review of Literature

ROBERT A. GLABE, M.D.

Plainview, Minnesota

TAIT'S dictum of 1911, "When in doubt, drain," has been, for more than two decades, the guide of many surgeons, but drainage has been practiced since the time abdominal surgery began. References are made to it in the old Greek literature. Mikulicz, about 1860, first expressed the rather daring and bold opinion that a gangrenous appendix might be removed and the peritoneal cavity closed without a drain (Cafritz).⁶ Jennings¹⁹ says that drainage of the abdomen seems to have remained more a matter of empiricism than of reason. There has been more attention directed, of late years, to the possibility of non-drainage and in 1929 W. J. Mayo was led by his observations to make a dictum to the effect that "When in doubt, don't drain." Warbasse feels that Mayo's dictum is becoming more popular.

Types of Drains

There is a great diversity of opinion as to what type of drain is to be used if drainage is instituted.

Jennings¹⁹ states that the ideal drain would be one which produced no exudate and caused no damage by its presence, which absorbed and removed the fluid present or about to form immediately and which could be removed without trauma to the surrounding structures. It should be highly and durably capillary and must be completely sterilizable. At present, we have no drain approximating these requirements, but Jennings feels that raffia has possibilities for the future.

Arnheim and Neuhof¹ feel that tube drainage should not be employed, for the following reasons:

1. There is no assurance that the tube remains where it is placed.
2. There is post-mortem evidence of residual abscesses about tube drains.
3. There is an irregular collapse of the walls of an abscess cavity or infected bed around

and beyond the tube with consequent tendency towards pocketing.

4. With drainage tubes, foul discharge and sloughing are commonly noted postoperatively.

They consider perfunctory gauze drainage in the same category as tubes, but add that gauze drainage is correct only if the infected area or areas are packed openly from the bottom. They seem to follow Tait but they use strips of iodoform gauze which are packed into all the recesses of the cavity or cavities or in non-abscess cases if appreciable purulent exudate exists or when the appendix or diseased viscus has been attached to an obviously infected bed. Drains are not disturbed until loosened by discharge, which they find is rarely profuse and rarely foul. The gradual shortening of the drain is begun usually about a week after the operation.

Spelman,²⁹ working with Hertzler, feels that rubber tubing drains delay formation of a thrombus in vessels while gauze may promote it. On the other hand, rubber tubing may cause rupture of blood vessels if it is allowed to come in contact with them over too long a period.

Tenopyr and Shafiroff³³ state that gauze is ideal for hemorrhagic abdominal areas where ligation is ineffective, but Shambaugh and Boggs²⁸ feel that exposed gauze should be avoided whenever possible. When the drain is for the control of bleeding and the hemostatic effect of the gauze is required, the cigaret type of drain should be employed and care be taken that only the gauze which is in direct contact with the bleeding tissue is left uncovered by the rubber casing.

Gauze packing like Mikulicz' drain or Joseph Price's cofferdam used in the pelvis for draining localized abscesses serves the purpose of draining but causes endless convalescence and dense and lasting adhesions (Ford Eastman).¹³

Chaffin⁸ feels that the only type of drainage of value is the capillary drainage, the value of which is only minimal and of short duration. He, therefore, believes that gravity or suction drainage alone is of value. Open tubes or drains

*Prize essay in contest open to Duluth internes and sponsored by the Duluth Surgical Society in 1938. Read before Duluth Surgical Society and at annual meeting of the Wabasha County Medical Society, Lake City, October 5, 1939.

afford outlet for much exudate under pressure but do not drain.

Summary.—At present, we have no ideal drain meeting the requirements of Jennings, chief of which are that the drain absorbs and removes the exudates well and does not produce damage to tissues.

Experimental Investigation of Drains

Several investigators have contributed much to the profession by their experimental studies on drainage.

Hertzler,¹⁸ in 1919, in his monograph on the peritoneum, described the changes occurring when the endothelium of the peritoneum is traumatized. He found, to begin with, that the endothelial cells are not easily removed for microscopic study and it is only when reactive processes are added to mechanical insults that the cells readily loosen. A great deal of energy must be applied to secure an abrasion by rubbing with a piece of gauze. Certainly, no manipulation with gauze within the range of operative technic is sufficient to dislodge the cells. Trauma, even to this extent, is not followed by reaction other than the formation of an exudate with prompt endothelialization. The bite of forceps and traction with sharp-pronged hooks are much more deleterious sources of trauma. With these instruments solution of continuity of the basement membrane may be produced which may be the source of permanent adhesions. A source of still more mischief is the ligation of pedicles, leaving an exposed stump which is capable of injuring normal surfaces with which it may come in contact. When the mechanical injury extends to a sufficient degree to cause death of tissue a reactive process follows. The dead tissue institutes the same sequence of symptoms that bacterial toxins produce.

When the processes of inflammation and wound healing coexist, the latter can become active only after the former has overcome the noxious agents. The tissues possess a certain capacity to prevent the growth and development of bacteria, but the conflict in the tissues may be so slight that it does not find expression in marked subjective or objective changes generally recognized as inflammation. The surgeon is apt to depend too much on the ability of the peritoneum to take care of a certain amount of infection because animal experimentation and clinical experience have shown that it is capable of do-

ing so. Did he realize that by just so much is final healing retarded he might manifest a greater reluctance in adding the additional burden. Devitalized tissue is as important as bacteria in producing minor disturbances in wound healing. There is no dividing line between the formation of fibrous tissues, the healing of wounds, and the formation of adhesions.

The rule is universal that what the peritoneum cannot absorb, it walls off or dies in the attempt. Any foreign body not capable of prompt absorption is walled off. Therefore, any foreign body placed in the peritoneal cavity to prevent adhesions must, most certainly, induce that which it was intended to prevent.

Yates,³⁶ in his Senn prize monograph of 1902, on abdominal drainage, conclusively demonstrated that drains do not drain after twenty-four hours.

In a series of dogs under sterile precautions, drains were inserted into one flank. The animals were allowed to recover and after stated time intervals incisions were made below the ensiform cartilage. The animals were placed in high Fowler's position and a solution of normal saline colored with carmine red was allowed to run in through the above opening. Control incisions were made in the opposite flank and a fresh drain was inserted at the time of the second procedure. In no case did the original drain discharge any of the injected colored fluid although there was always a flow from the new drain. Autopsy examination of the animals proved that the drains were completely walled off from the general peritoneal cavity, isolation of the drain occurring, usually, within four to six hours, being complete in twenty-four hours. It did not matter whether gauze, rubber, or a combination of both were used; the end-result was the same. The infected peritoneum preoperatively injected with virulent staphylococcus cultures reacted to foreign drainage in very much the same manner, but much more rapidly, in the process of encapsulation of the drain. Yates observed that animals with generalized peritonitis reacted to the presence of a drain by the severest type of inflammation. If these animals recovered, the areas encapsulating the drains consistently showed the invading organisms in the postoperative adhesions long after recovery occurred. Yates claimed that drainage for animals, suffering from generalized peritonitis, was more detrimental than beneficial.

Yates gives the necessary explanation for the profuse purulent discharge that soaks the gauze and is such a delight to the surgeon who believes he is actually removing toxic material from the cavity. The seropurulent discharge found on the dressing is in all cases a serous discharge, a part of the exudative phenomenon of the particular area of peritoneum irritated by a foreign substance (the drain) and contaminated by a foreign substance—as Councilman has shown by cocci that have travelled down the drain. This discharge will continue to flow as long as the drain remains in the cavity. Yates' graphic description of the gross and microscopic pathological changes that occur with peritoneal drainage follows:

"There is, at first, a serous exudate associated with local hyperemia. As the inflammatory reaction increases, a fibrinous exudate is formed and there is more intense local congestion and some edema. The serosa loses its luster and is finally covered with opaque fibrin. This fibrinous surface persists in the presence of smooth drains for at least seven days. Gauze drains, however, act differently. The fibrin becomes incorporated in the meshes, followed by an ingrowth of granulation tissue, so that when the gauze is removed, instead of leaving a smooth surface it is rough and bleeding, with fibrin and superficial tags of granulation tissue still clinging to portions of the gauze. The serous exudate is most abundant during the first few hours (four to six), when it becomes noticeably less in amount and concomitantly there begins the visible deposit of fibrin. This serous excess is manifested during this time by the wetting of the abdominal dressings and by the appearance of an increased amount of intraperitoneal fluid which disappears about the time of isolation of the drain by adhesions is affected. The character of the adhesions varies with the nature of the drain—the greater and more prolonged the irritation the more intense the reaction and the finer the adhesions. All serous surfaces, visceral or parietal, react similarly."

Any foreign body allowed to remain in the peritoneal cavity results in adhesions. Blood clots beneath the peritoneum undergo organization and produce adhesions.

Hertzler stated that if the edges of the peritoneum are carefully everted into the incisional wound at the time of closure, allowing only a small suture wound to present toward the peritoneal cavity, adhesions are prevented with a considerable degree of certainty. His observations are sufficient to demonstrate the importance of the cut edge of the peritoneum whether by the teeth of forceps or marked blunt trauma inflicted by retraction in inverting adhesions. All

that the surgeon can do to prevent adhesions is to operate with the utmost gentleness, placing the minimum of foreign bodies of all sorts, either temporary or permanent, within the abdominal cavity, and cover the denuded surface as carefully as possible.

Yates, in his conclusions, states that drainage of the general peritoneal cavity is both physically and physiologically impossible. He says that "peritoneal drainage must be local and unless there is something to be gained by rendering such an area extraperitoneal or by making such an area a safe path of least resistance leading outside the body, there is, aside from hemostasis, no justification for its use."

Indications for Drainage

Today, the main controversy is not how to drain but whether or not drainage is necessary, and if it is necessary, when it should be done. A general review of the literature on appendicitis reveals the fact that no amount of analysis allows for any dogmatic statements on the question of drainage. The great bulk of the literature on the drainage of the abdomen deals specifically with appendicitis. However, the general conclusions concerning drainage of diseases of the appendix will hold for many other diseases of the abdominal cavity. It is a generally accepted statement that drainage of the entire abdominal cavity is impossible and therefore of no value in peritonitis.

Richter²⁷ of New York and Hustinx (Willis and Mora)³⁵ of Netherlands feel that the presence of a serous or purulent fluid is not an indication for drainage, but rather the possibility of not being able to remove for one reason or another the entire source of infection.

Ford Eastman¹³ uses the indications of British Surgeons for draining: uncontrollable oozing, pyogenic membrane, or fecal fistula, present or imminent. Muelleder²⁴ of Germany adds the following to his list of definite indications: Children under ten years of age and patients over fifty years of age, when the intestinal coils are covered with much deposit and are agglutinated (pyogenic membrane), when the foul-smelling exudate is present in large amounts and when the pus from the pouch of Douglas, from the region of the liver, from the gastric gutter, or from the left side, flows toward the incisional wound. He therefore drains most of his cases.

It is the almost universal opinion of surgeons contributing to the literature, that a chronic localized abscess should be drained. For some, including Trinca,³⁴ Rhodes and Fernald,²⁶ and others, including Andrews, Miller, and Gatch as quoted by Rhodes and Fernald, a walled-off abscess is the lone indication for drainage. Straus and Tomarkin³² and Willis and Mora,³⁵ among others^{11,16} feel that a contaminated peritoneal cavity should be included with the chronic abscess for drainage indications. Arnheim and Neuhoof,¹ Gile and Bower,¹⁵ and others^{9,12,17,22,24} follow Tait's dictum of drainage when in doubt.

The rationale of draining is based on the prevalent, but probably erroneous, belief that though the absorption power of the peritoneum is, in comparison with other serous membranes, very great, the mechanical release through a drain of infectious substances is bound to speed up recovery and to facilitate healing (Cafritz).⁶

Weil says that "peritoneal exudation is evidently the sole means of defense possessed by the abdominal cavity." Murphy considers the removal of exudate from the abdominal cavity a great error, as the necessary defensive antibodies are also removed together with the exudate. He believes that the purulent exudations contain defensive elements and that the removal is harmful to the patient. Peterman agrees with Murphy's views as far as early exudates are concerned. He believes, however, that when the exudate becomes ichorous and purulent, and contains intestinal matter, necrotic tissues or other foreign matter, the exudate does more harm than good (Breitmann).²⁹

Bunch and Doughty⁵ concur in the belief that the inflammatory exudate so often found in the peritoneal cavity at operation is not protective and germicidal, but may be harmful and should always be removed.

Breitmann³ feels that in cases of peritonitis the water metabolism of the body is greatly disturbed by the loss of fluids which Rhodes and Fernald,²⁶ agreeing with Weil and Breitmann, believe contain the body defensive elements.

Grossan¹² favors drainage because he feels it relieves tension and protects against possible intestinal leak, but he urges caution in using drains because it must be remembered that a drain is an ordinary foreign body and must be placed in positions that are harmless to the tissues.

Summary.—Surgeons differ in their opinions

concerning the indications and necessities for drainage. Most surgeons probably feel much the same as Peterman in that early exudates are beneficial but that later exudates, ichorous and purulent, consisting of intestinal matter, necrotic tissue or other foreign material, are harmful and should be removed. All agree that a chronic localized abscess should be drained.

Factors Affecting Results in Analyses

Many articles in the literature on drainage and appendicitis were purposely free from any statistics because it was felt that there were too many factors involved in analyzing a series of cases, so that statistics on morbidity and mortality have little or no value.

Willis and Mora³⁵ and likewise Colt and Morrison¹⁰ feel that drainage has no effect upon the mortality rate but that the rate is more dependent upon the duration of symptoms before operation, the extent of the pathological changes, the virulence of the offending organisms and the resistance of the patient. It is interesting to note, however, that Colt and Morrison had a mortality rate distinctly lower in their series of non-drained cases.

Studying the relationship between the duration of symptoms and the mortality rate, Stanton³¹ has graphically shown that, in a compilation of cases from recent literature, after the attack has begun, the mortality rate of acute appendicitis varies greatly with the time that elapses before operation.

Day of Operation After Attack Began	No. of Cases	Deaths	Mortality Percent- age
First day	1,507	20	1.3
Second day	912	33	3.6
Third day	663	56	8.9
Fourth day	365	46	12.9
Fifth day	442	49	11.6
Sixth day	346	29	8.4
Seventh, eighth, ninth days	178	5	2.8
Tenth day or later	288	7	2.4
Total	4,692	245	5.22

From these figures if the rule—operate before the third day or wait until after the sixth day from onset—were blindly followed, the mortality

rate would be cut in half. The mortality rate in most series of cases does not amount to more than 3 per cent.

Another factor in making the mortality rate in the drained cases seem higher than in the non-drained cases is that most surgeons drain the severest cases even when they treat the rest of their cases by non-drainage.

Kirtley and Daniel²¹ feel that the age of the patient is important in analyzing statistics. Their review of the literature showed a mortality rate in children under ten to be 23 per cent, and above the age of fifty years to be 15 per cent and rising with age. The mortality rates are lower in the age groups between these limits, being lowest in the age group of fifteen to twenty-five years, where it is 3 per cent.

Analysis of Methods and Results

Glasscock¹⁶ reported 457 non-drainage cases with one death due to bleeding from the slipping of a ligature on the mesoappendix. The drained cases had a mortality of 11 per cent, but he stated he generally drains the worst cases. McClure and Altemeier²² also had a mortality rate of about 11 per cent in their series of 252 consecutive cases of acute perforated appendicitis with peritonitis. All of their cases were drained.

All surgeons contributing to the literature agreed that a chronic localized abscess should be drained. Extraperitoneal drainage apparently gave the best results. Shambaugh and Boggs⁶ use a simple rubber tube to produce a sinus tract through which an underlying abscess may later be evacuated extraperitoneally. The drain is usually removed the fourth or fifth day and the abscess ruptured through the resulting sinus tract. When they insert a drain into the infected peritoneum in which one suspects that an abscess would form if drainage were omitted, the drain is not removed before the fourth day or before a structural tract is formed. Drainage of cul-de-sac abscesses per rectum is condemned. Most surgeons treating an abscess remove the pus by aspiration and sponge, dissect out and remove the appendix or source of infection if possible, insert drains and close up the abdomen.

Breitmann³ inserts one drainage tube between the omentum and the abdominal wall and feels he accomplishes as much as if he inserted a tube into the pouch of Douglas. The tube is removed the fifth to the seventh day. He states, however, that he does not circumvent the formation of ad-

hesions. Buchbinder⁴ agrees with Breitmann and follows the same procedure.

Newell²⁵ tried to treat all his cases alike with the same indications. He had fifty-six cases, twenty-three of which were not drained. There were no deaths in this group not drained, although there were eight deaths in the thirty-three drained cases.

Herrick¹⁷ treated 217 cases of acute appendicitis with peritonitis by immediate surgery and drainage. In his series he had five deaths—a mortality of 1.84 per cent.

Jones²⁰ treats his cases by appendicostomy with a catheter inserted into the appendiceal stump. Nourishments are given through the catheter and nothing per os for as long as perhaps five days. The suture through the skin and the tube is usually removed about the sixth or seventh day, and the tube is permitted to come out spontaneously. No fecal fistulae have ever developed. He maintains normal physiology is more closely approached than by any other method employed. In a series of seventy-five cases he had a mortality of but 1.4 per cent. He reports that Wilkie of Edinburgh and Gatch have had similar experiences employing this method.

Cafritz⁶ referred to Marchini of Italy for figures on drainage and peritonitis. In this series of 301 cases of localized peritonitis, 184 were drained. There were nine deaths, a mortality rate of 4.88 per cent. One hundred and seventeen cases were not drained, with two deaths, a mortality percentage of 1.71. One hundred and one of the 142 cases of diffuse peritonitis were drained. There were thirty-one deaths, a mortality percentage of 30.69. Seven deaths, a mortality rate of 17.07 per cent, occurred in the forty-one non-drained cases of diffuse peritonitis.

One of the most interesting contributions to the subject of appendicitis and drainage was made by Cayford⁷ in his review of 614 cases seen at the Montreal General Hospital during the years 1931-1933. The average duration of illness prior to operation was 2.1 days. The patients averaged 15.99 days in the hospital. There were twenty-one deaths, a mortality percentage of 3.42. The patients were divided into three groups.

It will be observed that in Group B the drained group had a hospital stay of about seven days more than the non-drained group and the mortality percentage is about three times as great.

GROUP A. Acute diffuse or acute suppurative appendicitis, in which little or no inflammatory process extended to the surrounding tissues. No drainage.

Number of cases.....	266
Average days in hospital.....	11.34
Wound infections.....	2
Death	1

The fatal case was that of a female, aged 28, who had suffered from general debility associated with long-standing kidney disease. She died on the thirteenth day after operation with acute gangrenous cystitis with uremia.

GROUP B. Spreading or diffuse peritonitis was present.

In each case free fluid or free pus was found at operation. In each there was a pathological report of acute suppurative, acute gangrenous, or acute perforative appendicitis.

Number of cases.....	265
With drainage	
Number of cases.....	111
Average days in hospital.....	21.42
Deaths (9.01%).....	10
Complications	
Wound infections.....	5
Fecal fistulae.....	2
Residual abscess.....	2
Deaths: Generalized peritonitis usually uncomplicated.	
Without drainage	
Number of cases.....	154
Average days in hospital.....	13.41
Deaths (3.24%).....	5
Complications	
Wound infections.....	12
Residual abscesses.....	3
Deaths: Four due to general peritonitis and one due to cellulitis extending from the incisional wound.	

GROUP C. Acute appendicitis with localized abscess. In the drained cases the abscess cavity was evacuated by suction and moist gauze, and the abdomen closed with the application of liquid paraffin.

With drainage	
Number of cases.....	54
Average days in hospital.....	24.33
Deaths (1.85%).....	1
Complications	
Wound infections.....	5
Secondary abscesses.....	2
Death: A man, aged 37, who died the sixth day postoperatively with paralytic ileus complicated by bronchopneumonia.	
Without drainage	
Number of cases.....	21
Average days in hospital.....	22.9
Deaths	0
Complications	
Wound infections.....	2

There is very little difference in the figures covering the group of cases of acute appendicitis with localized abscess except that complications were more common in the drained group and there was one death.

Summary.—The mortality rate in most series of appendicitis cases drained or undrained usually is about 3 per cent, while the rate is about 11 per cent in the drained cases. Many factors enter into deductions made from analyses of series but cases treated by non-drainage seem to have lower morbidity and mortality rates. Much may depend upon the surgeon alone.

Complications of Drainage

Tenopyr and Shafiroff³³ state in answer to the question of the dangers following drainage in patients who recover, that the incidence of intestinal obstruction, herniation, adhesions and fistula formation is very much the penalty for the use of drains.

Mensing,²³ Sperling and Wangenstein,³⁰ and others^{2,6,7,13,14,19,24,25,26,29,32,35} also feel that the insertion of drains leads to more complications and longer convalescences than non-drainage.

Ford Eastman¹³ feels that incisional hernias are due to cellulitis slough of important abdominal fascia and to muscular atrophy from disuse dependent upon long suppuration.

Breitmann³ considers it very erroneous to apply drainage and tampons at the spot of intestinal sutures because of the danger of fistula formation, or in proximity of blood vessels, as there is danger of necrosis of the walls, leading to bleeding. Proximity of drainage tubes to the walls of the intestines may cause perforation.

Mueller²⁴ says that abscess formation cannot always be avoided by the insertion of a drainage tube into the pouch of Douglas. He is certain that primary closure of the abdominal wall is well suited to make the disease picture milder, as well as to shorten the duration of healing.

Bancroft² obtained results as shown in the accompanying table, in comparing the complications in eighty-seven drained and eighty-seven non-drained cases.

Glascok¹⁶ noted that 50 per cent of his ruptured non-drained cases presented wound infections and he expressed the opinion that it might be advisable to drain the wound down to the peritoneum. Every drained case left the hospital with a discharging wound. In the non-drained

SURGICAL DRAINAGE OF THE ABDOMEN—GLABE

	Drained		Not drained	
	No.	Per cent	No.	Per cent
Infected wounds	12	10.5	3	2.6
Hematomata	2	1.6	9	7.8
Secondary abdominal abscesses	5	4.6	1	0.8
Intestinal obstruction	1	0.8	1	0.8
Paralytic ileus	2	1.6	0	0.0
Fecal fistula	3	2.6	0	0.0

ruptured group, when no infection occurred, the patient's temperature became normal on the third or fourth day, as compared with the twelfth or thirteenth day for the group that was drained. He considered this to be an accurate indication of the ability of the peritoneum to take care of itself after the source of infection had been removed and felt it supplied further evidence that the drain acts as an offending agent. In his series, the earlier the drain was removed the more readily the temperature returned to normal. The cases which were drained had a hospital stay of about four and one-half days longer than the non-drained cases. Although no fecal fistulae developed in the non-drained group, four occurred in the drained series, three of them in the gangrenous non-ruptured cases. He felt that this latter type of patient should be treated as a simple acute appendicitis not necessitating drainage.

Straus and Tomarkin³² studied 1,325 consecutive cases of acute appendicitis in relationship to

drainage. Their cases were treated in three different ways—abdominal drainage, subfascial drainage, and non-drainage. The non-drained group had an average hospital stay much shorter than the drained groups.

Non-drainage group10.7 days
Subfascial drainage group.....15.3 days
Abdominal drainage group.....15.6 days

Probably delayed healing of the abdominal walls was the only factor in prolonging hospitalization. Of the 1,325 cases, 462 had abdominal drainage, 794 no drainage and 69 had subfascial drainage—863 cases, therefore, in which there was no abdominal drainage. The mortality rate of the abdominally drained group was 8.03 per cent in comparison to 2.21 per cent in the non-drained group. They realized that their more severe cases were drained.

There were 187 patients with ruptured appendices, twenty of whom died. Of the 187, 110 were drained intra-abdominally. Sixteen deaths occurred in this group, a mortality percentage of 14.5. Twenty-five cases were drained subfascially and fifty-two had no drainage—a total of seventy-seven without peritoneal drainage. The four deaths made the mortality percentage 5.2. Thirty-one of the 187 patients had drainage alone at operation. Six of these patients, or 19.3 per cent, died. The average duration of symptoms before operation was 7.9 days.

The following summarizes the complications:

Abdomen drained			Abdomen not drained					
	No.	Per cent	No.	Total Per cent	No.	No drainage Per cent	Subfascial Drainage No.	Per cent
Pelvic abscess	33	7.1	21	2.4	10	1.2	11	15.9
Wound infection	462	100.	197	22.8	128	16.18	69	100.
Fecal fistula	16	3.4	5	.57	4	.5	1	1.4
Intestinal obstruction	4	.86	2	.2	2	.25	0	
Paralytic ileus	5	1.08	4	.46	3	.38	1	1.4
Generalized peritonitis	5	1.08	11	1.2	11	1.38	0	
Lobar pneumonia	10	2.1	6	.6	6	.7	0	
Bronchopneumonia	15	3.2	8	.9	8	1.0	0	
Emboic death	2	.43	0		0		0	

They stated that every drained case might be considered a wound infection.

Exclusive of wound infections, there were 139 cases, or 30 per cent, complications in the drained group, while there were 108 in the non-drained group, or 12.5 per cent.

Summary.—Statistics such as those contributed by Bancroft, Cayford, Straus, and Tomarkin, and Glascock reveal the danger of drains in themselves because of their foreign body effects. These dangers or complications include possible intestinal obstruction, herniation, adhesions, fistula formation, rupture of blood vessels, embolism, infected wounds, secondary abscesses, paralytic ileus and pneumonia.

Summary

1. At present there is not an ideal drain available. Most drains do not well remove or absorb exudates and most are likely to produce damage to adjacent tissues.

2. Yates and Hertzler especially have experimentally shown the processes developing and ensuing after the insertion of drains or foreign bodies into the abdominal cavity. Drains are quite ineffective after four or six hours and are completely walled off in twenty-four hours.

3. Surgeons differ greatly as to their opinions regarding indications and necessities for drainage. All agree, however, that a chronic localized abscess necessitates drainage.

4. Factors such as duration of symptoms before operation, the virulence of the organisms, resistance of the patient, age of the patient, and the tendency of surgeons to drain their severest cases forbid making any dogmatic statements regarding drainage or non-drainage.

5. With cases controlled as well as possible, non-drained cases seem to have lower morbidity and mortality rates than drained cases.

6. What are probable complications of drainage is the greatest argument against the use of drains.

Conclusions

The literature is full of contradicting articles on the subject of drainage of the abdominal cavity, especially in relationship to appendicitis, probably because there are so many factors influencing any study restricted to this one aspect, but after reviewing the literature it seems that a diversion from Tait's dictum to that of Mayo's

"When in doubt, don't drain" is quite imperative. Probably two unbiased conclusions may be drawn:

1. Drainage is perhaps indicated in chronic localized abscess alone.

2. Primary closure of the abdomen makes the disease picture milder, as well as shortens the duration of convalescence.

MANAGEMENT OF ACUTE ABDOMINAL EMERGENCIES*

JOHN M. WAUGH, M.D.

Rochester, Minnesota

THE surgical treatment of acute abdominal emergencies is, without question, the most interesting and fascinating field in which the general surgeon may delve. For its proper execution the surgeon is required to have not only technical skill, but also mature judgment coupled with a background of conservatism. Surely we cannot all hope to be blessed with all three of these attributes, but it is very easy for all of us to assume the last, namely, conservatism. In dealing with these emergencies, we should remember first and foremost that we are usually conducting a lifesaving operation and that the emphasis should be on this rather than on those factors associated with elective operation. Thus, the prime motive of the operation is to save the patient's life and the operation should be so conducted that this end is achieved. After the emergency situation has been controlled by a conservative procedure, one can direct his attention to the diseased organ and, if necessary, a second operation correcting the pathologic condition can be performed with a greatly decreased risk over attempting to cope with both at the same time. Such an attitude of conservatism can do much toward lowering the mortality accompanying acute abdominal operation. In this paper I shall discuss the surgical treatment of five of the more common acute surgical conditions arising in the abdomen.

Acutely Perforated Peptic Ulcer

The results at The Mayo Clinic and elsewhere definitely bear out the advisability of conservative surgical procedures in the management of acutely perforated peptic ulcer. The more radical procedures, such as gastro-enterostomy, pyloroplasty or resection, are accompanied by twice the mortality of simple closure followed by reinforcement of the region with omentum, which is, as a rule, the advisable procedure. In the

presence of marked scarring and a history of pyloric obstruction, if the perforation is of short duration and the patient's condition warrants a more lengthy procedure, gastro-enterostomy, pyloroplasty or gastroduodenostomy may be considered. Because of the marked inflammation usually present, any local procedure other than closure will be difficult technically. It is well to remember that few of these patients have had adequate medical management prior to perforation. Before subjecting them to the increased hazard of a long surgical procedure with the attendant danger of shock, a fair trial of conservative treatment seems judicious. Guthrie and Sharer have shown that simple closure of the ulcer results in 80 per cent cures and in only 20 per cent was there a recurrence of symptoms.

The anesthetic of choice is a combination of gas and ether. Because of the marked abdominal rigidity, relaxation is usually difficult and will require considerable ether to attain it. Spinal anesthesia is contraindicated because these patients are frequently in shock.

Most often the perforation will be easily discernible on the anterior wall of the first portion of the duodenum near the superior border. The sutures should be placed in the long axis of the duodenum so that when they are tied they will not tend to constrict the lumen. If the opening is too friable to close satisfactorily, the omentum or round ligament may be sutured over the area. One should always be on the lookout for multiple perforations.

If the perforation is closed within six or eight hours, probably in most instances drainage of the peritoneal cavity is not necessary if care is taken to evacuate the accumulated fluid with the mechanical sucker at the time of operation. If there is considerable fluid present or the perforation is of long duration, it is probably safer to drain, not only subhepatically, but also supra-

*From the Division of Surgery, The Mayo Clinic, Rochester, Minnesota.

pubically. I have never seen any ill effects following the use of the soft Penrose type of drain.

If the patient is first seen by the surgeon twenty-four hours or more after the onset and there is a tendency toward localization of the process, the best treatment may be conservative with the continuous nasal suction tube in the stomach. Under these circumstances operative interference might only add insult to injury by breaking open a closure which nature had already well effected.

Perforating malignant gastric lesions are occasionally encountered. Because of their nature, simple closure is technically impossible and resection is necessary with attendant high mortality. If perforation complicates malignant gastric lesions, it is usually subacute. If the condition is recognized it is best treated conservatively. Resection should be undertaken after the acute phase has subsided.

The mortality accompanying perforated peptic ulcer is in direct proportion to the time elapsed before surgical closure and to the magnitude of the operative procedure.

Acute Cholecystitis

At present there is considerable controversy over the management of the acutely inflamed gallbladder, some advocating immediate operation, others conservative treatment during the acute attack followed by operation after the acute symptoms have subsided. A few years ago only an occasional patient with clinically acute cholecystitis was operated on at The Mayo Clinic. Now, probably 50 per cent of the patients entering the hospitals as emergencies with a diagnosis of acute cholecystitis are operated on during the acute phase. The proponents of early operation advocate it for the following reasons:

1. Technically, it is easier because fibrinous adhesions are encountered rather than fibrous which are the rule later.

2. It does away with the danger of perforation into the stomach or duodenum or general peritoneal cavity with generalized peritonitis.

3. There is a lower mortality or morbidity.

On the other hand, the opponents of early operation give the following reasons for their attitude:

1. Technically, early operation is more difficult because of edema and bleeding. For this reason the common duct will be more frequently

injured and many patients will be subjected to cholecystostomy whereas if operation were postponed cholecystectomy could be safely undertaken.

2. Pathologic conditions of the common duct will be more frequently overlooked in early operation, because, often, icterus cannot be detected when the patient is first examined. If icterus becomes evident after operation, the surgeon will be in a quandary as to whether there are common duct stones or injury.

3. Rarely does generalized peritonitis result from acute cholecystitis.

4. Conservative treatment results in lower mortality and morbidity.

Personally, I have been pursuing a middle-of-the-road policy and have tried to individualize the treatment of acute cholecystitis. Those patients with considerable elevation of the temperature and pulse rate, accompanied by pronounced local findings, have been operated on immediately and usually cholecystectomy has been performed without difficulty. Occasionally the operation was difficult and rarely cholecystostomy proved the operative procedure of choice. On the other hand, the milder forms of cholecystitis have been treated conservatively during the acute attack and operated on in the interval at the patient's convenience. I am sure that the occasional operator will encounter more difficulty with early operation than later and, of necessity, will perform cholecystostomy where cholecystectomy could have been undertaken safely after the acute symptoms had subsided. In choosing between cholecystectomy and cholecystostomy, one should recall that the latter, more conservative procedure will relieve about 60 per cent of patients and only approximately 40 per cent will require further operation because of a recurrence of symptoms.

Acute and subacute pancreatitis are seen, usually accompanying acute cholecystitis. The milder forms can be diagnosed frequently by pain and tenderness in the left upper quadrant and by finding an elevated serum lipase. The more severe classic form is rarely diagnosed before exploration, because it is difficult to distinguish from the generalized peritonitis resulting from perforated peptic ulcer or a perforated appendix. If a definite preoperative diagnosis can be made, conservative treatment is in order, with explora-

tion of the gallbladder and ducts later, after the acute phase has subsided. If the diagnosis is made at exploration and the patient's condition is grave, drains should be placed down to the pancreas, getting out as quickly as possible. Of course, if the patient is in good condition, the needed corrective operation on the bile passages may be undertaken without undue risk. This will usually amount to exploration of the common duct with T tube drainage and cholecystostomy or cholecystectomy with adequate drainage over the region of the head of the pancreas.

Acute Intestinal Obstruction

When confronted with acute intestinal obstruction, one should determine first whether it is the large or the small intestine that is involved. Much abdominal distention with cramps and very little or no vomiting usually mean that the large intestine is involved; an annular carcinoma in the sigmoid is the most frequent cause. Often, conservative treatment, hot stupes to the abdomen and enemas in the knee-chest position, will be successful in relieving the acute phase of this type of obstruction. Duodenal drainage by means of the inlying nasal tube is rarely of any use in obstruction of the large intestine because the ileocecal valve permits very little fluid to back up through it into the ileum, even when the colon is much distended and there is considerable pressure in the cecum. Usually, one is safe in continuing conservative measures for twenty-four hours if the temperature and pulse are within normal limits. If there is no improvement at the end of this interval or if there is any tendency toward elevation of the pulse and temperature, one should undertake cecostomy immediately. This can be done satisfactorily under local anesthesia using a McBurney incision and the Witzel technic with a large No. 30 catheter. Exploration is not justified and a definite aseptic technic should be used, remembering that the fluid in the cecum is under terrific pressure. The patient will experience immediate relief and within twenty-four to forty-eight hours the abdomen is usually flat. It is not uncommon, after decompression has been effected, for the large bowel to regain its tonus and for the patient to empty his colon naturally. In ten days or so it is usually safe to attack the obstructing process directly.

On the other hand, if there is little distention with cramps and much vomiting, the small in-

testine is probably obstructed. The plain roentgenogram of the abdomen is of inestimable value, not only in helping to locate the obstruction in the large or small intestine by the pattern of the contained gas and fluid, but also in determining the efficiency of any type of therapy. For this reason, daily roentgenograms should be made. If the obstruction is of short duration with normal temperature and pulse and there is no evidence of strangulation as evidenced by rebound tenderness, one is justified in trying to decompress the intestine with duodenal drainage by means of the inlying nasal catheter.

If there is no definite improvement within twenty-four hours as evidenced by both roentgenographic and physical examination, or if there is a rise in temperature or pulse rate or a suspicion of strangulation, exploration should be undertaken without hesitation. On opening the peritoneal cavity, serous fluid usually escapes and if it is serosanguineous, one should look out for strangulation. In any acute obstruction involving the small intestine, unless it is known to be of an inflammatory nature, I believe that gentle exploration is advisable to rule out definitely strangulation or a closed loop type of obstruction. If an adhesion is found to be the cause, this may be severed and usually a Witzel type of enterostomy is advisable in the dilated intestine above the obstruction. A No. 16 or 18 catheter is large enough. If a strangulated loop is found and the patient's condition is good, one may proceed with resection and immediate anastomosis with temporary enterostomy above the anastomosis. On the other hand, if the patient's condition is critical, one should be satisfied with enterostomy and exteriorization of the strangulated loop, re-establishing the intestinal continuity later when the patient's condition has improved.

Adynamic ileus is characterized by marked distention, vomiting and absence of both peristalsis and cramps. This type is most often seen post-operatively. It is in this type of disorder, as well as obstruction of the small intestine due to inflammatory processes, peritonitis, and so forth, that the various forms of nasal tube decompression have proved successful in my experience. Rarely will duodenal drainage or the Miller-Abbott tube aid in relieving obstructions of the large bowel. Wangenstein, in popularizing duodenal drainage, pointed out its indications and contraindications, but in the enthusiasm for it

there has been a tendency to use it blindly in all obstructions and to rely on it too long before intervening surgically. In dealing with any type of intestinal obstruction the administration of barium by mouth is contraindicated and a dangerous practice. Transfusions and fluids by vein are frequently lifesaving measures in intestinal obstruction.

Strangulated Hernia

The mortality accompanying repair of strangulated hernia is in the neighborhood of 10 per cent as compared with 0.3 per cent in uncomplicated cases of inguinal hernia (latter figure from The Mayo Clinic during 1937 and 1938). Thus, the best treatment for strangulated hernia is prophylactic and for this reason one should not hesitate to advise early repair of all hernias, no matter how insignificant they may seem at the time of examination, provided that the patient is a reasonable operative risk. In dealing with strangulated hernia, the prime motive of the operation is to relieve the intestinal obstruction and to determine the viability of the strangulated loop. Repair of the hernia is of secondary importance and one should not jeopardize the patient's chance of recovery by prolonging the procedure until a satisfactory closure is effected. If the patient is in a grave condition and has a gangrenous loop of intestine, operation should consist only in the exteriorization of the involved portion of the intestine, thus allowing drainage and relief of the obstruction. At a later date, intestinal continuity may be re-established when the patient's condition is improved and the hernia may be repaired without undue risk.

Appendicitis

There is no question about the proper treatment of early acute appendicitis prior to perforation, but there is a great deal of controversy as to the proper procedure in the face of perforation and its complications. If signs of localization are not present in the face of a perforated appendix with generalized peritonitis, I feel the proper procedure is immediate operation with drainage of the peritoneal cavity. If the patient's condition warrants appendectomy and if it can be accomplished without trauma or spread of infection owing to the breaking down of protective adhesions, appendectomy is permissible. Rarely, a patient will be admitted in such poor condition that any operative procedure

would be attended by great risk. Under these circumstances, conservative treatment is indicated during which an attempt is made to rehabilitate the patient and to determine what method of management will be best for that type of case.

If, on the other hand, there are signs of localization of the inflammatory process, conservative treatment is instituted under close observation until the seventh or eighth day after perforation at which time the patient has greatest immunity to the infection. At this time the abscess is drained unless, as will occasionally happen, there is resorption of the inflammatory mass. Again, in this case, an attempt should not be made to remove the appendix unless it is free in the abscess cavity and can be removed without breaking down protective adhesions. If appendectomy has not been accomplished, the patient is advised to return for it in two to three months, unless acute symptoms ensue during this period; if such occur, operation, of course, is undertaken immediately, to obviate the occurrence of a second perforation.

All patients with peritonitis, whether operated on or treated conservatively, are handled in essentially the same way. Nothing is administered by mouth until flatus is passing per rectum and distention is relieved. If there is vomiting, continuous duodenal drainage is instituted. Fluids are administered subcutaneously and by vein. Personally, I feel that small transfusions of 250 to 300 c.c. of blood with oxygen therapy by mask or by tent, are the most potent weapons in treating peritonitis. Simple elevation by placing 10 inch blocks under the head of the patient's bed is just as efficient as the use of Fowler's springs, more comfortable for the patient and easier from the standpoint of nursing. Morphine is administered in adequate doses every three to four hours. Enemas and proctoclysis are avoided. A rectal tube is inserted for a few minutes every four hours. If abdominal distention is present, hot turpentine stupes are in order. Priestley^{4,5} has shown that Weinberg's serum is of definite aid in the treatment of peritonitis secondary to a perforated appendix.

The Use of the Sedimentation Rate in Diagnosis

The research that Bannick and his collaborators² undertook at The Mayo Clinic a few years ago in regard to the sedimentation rate of the

red blood cells in acute abdominal disease has done much toward clarifying the position that should be occupied by this valuable test in the differential diagnosis of acute abdominal conditions and has pointed the way to the prominent part this simple laboratory procedure will undoubtedly play in the future. Bannick found, after close observation in a number of cases in which the diagnosis was substantiated either by operation or bacteriologically, that:

1. The sedimentation rate is normal in acute simple appendicitis, but after rupture, with either localized or generalized peritonitis or abscess, the rate becomes elevated. It is readily seen how this test, which will give definite information as to the presence or absence of perforation, will be of unlimited value in the surgical management of acute appendicitis.

2. Occasionally, in cases of acute pelvic inflammatory disease, the sedimentation rate will be within normal limits during the first forty-eight hours after the onset of abdominal pain. Beyond this time it is invariably elevated. This finding shows that one must not rely on a normal sedimentation rate in distinguishing appendicitis and acute pelvic disease within the time limit stated.

3. In acute cholecystitis and acute infections of the urinary tract, the sedimentation rate was usually elevated, even early in the disease, but not invariably so.

Bannick¹ hastened to caution that the sedimentation rate, although more trustworthy than

the white blood count, is not infallible and certainly should take second place to a careful history and physical examination.

Summary

Emergency operations are usually lifesaving procedures and the surgeon should choose the most conservative procedure available which is compatible with the problem at hand. Corrective operation can frequently be advantageously delayed until the patient has recovered from the emergency lifesaving operation with less risk to the patient and a better probability of carrying out a complete and curative procedure. This is especially true in acutely perforated peptic ulcer and acute intestinal obstruction. It also holds in the severe grades of acute cholecystitis, acute appendicitis and strangulated hernia.

The sedimentation rate is of definite value in the differential diagnosis of acute abdominal diseases.

THE TREATMENT OF MENTAL DEFECTIVES IN MINNESOTA*

E. J. ENGBERG, M.D., Superintendent, Minnesota School for Feeble-minded
Faribault, Minnesota

THE experience of years has changed the original idea that the purpose of state institutions for the care and treatment of mental defectives is to provide segregation for life, although this is still necessary for the majority of those committed who are idiots or imbeciles. Idiots are individuals with intelligence quotients up to 24 per cent (Kuhlmann scale) and mental ages up to two years; imbeciles are those with intelligence quotients from 25 to 49 per cent and mental

ages from three to six years. However, with the more frequent recognition of the high grade mental defectives or morons with mental ages from seven to eleven years and intelligence quotients from 50 to 74 per cent, larger numbers of this type are, because of associated social problems, being admitted to the institutions for feeble-minded. Unfortunately, the public usually understands that the term moron describes a person guilty of some terrible sex crime. This may be because the lay press tends to refer to such perpetrators as morons. These crimes, usually,

*Read at the annual meeting of the Minnesota State Medical Association May 31, 1939.

however, are not committed by feeble-minded persons but by individuals with psychopathic personalities requiring treatment and control different from that needed by mental defectives.

Many of the moron group can return to their communities to be entirely or partly self-supporting under supervision. This is highly desirable both for humanitarian and economic reasons. Expanded and improved school departments have increased the number of these children who may have the benefit of proper treatment in state institutions through shortening the average time spent there for training. For this reason, each child is carefully studied to determine the amount of academic work that should be taught. The type of vocational training to be given is determined in part by the special aptitude present and in part by whether the individual will return to a rural or urban community. Special attention is given to recognize and correct improper habits and emotional reactions. The educational and recreational programs are planned to try to develop a proper social adjustment.

The new arrival sent to our institution by the Board of Control* after commitment enters first the hospital for fourteen days of isolation to prevent the spread of contagious diseases. During this time, routine physical, neurological, and psychiatric examinations are made as well as laboratory studies of the blood, urine, smears from the nose and throat, the blood Wassermann test, the Mantoux test, an x-ray of the lungs to prove the presence or absence of active tuberculosis, as well as spinal fluid examinations, when indicated. Those unprotected against smallpox are vaccinated upon arrival. Each case is reviewed by the physician in charge with the entire medical staff at the weekly medical rounds and agreement is reached as to the cause and diagnosis of the mental defect present, and of the treatment of physical disabilities present. When necessary, arrangements are made for consultation with specialists in various fields. A full-time dentist checks the condition of the teeth of each child upon admission and takes care of dental needs while in the institution. Special attention is given to provide an adequate and

well-balanced diet, together with special diets when required.

Each week a general Staff Case Conference occurs at which are present the resident physicians, the principal of the school department, the social service workers, and the dormitory division supervisors, with the superintendent presiding. Each new arrival is presented in person with medical, social, and school histories, except for low grades who are cleared by record only. It is determined to which dormitory the child will be assigned; the type of formal training, if any, to be given; or the kind of institutional work to be assigned if training is not necessary or desirable. The newly admitted fall into one of six classes:

1. For segregation, low grade defectives and those seriously crippled. These require continuous nursing care.
2. For segregation, low grade defectives able to do some type of institution work.
3. For segregation, chronic delinquents who are assigned to special locked buildings for each sex.
4. For sterilization and immediate return to the community.
5. Defective delinquent girls transferred for sterilization from the State School for Delinquent Girls at Sauk Center.
6. Those desirable for placement after completing period of training.

The last group is referred to the School Department. On April 25, 1939, this consisted of:

I. *Teachers:*

One principal and an assistant.
One librarian.
One teacher of music and one bandmaster.
Six pre-vocational or manual arts teachers.
Six industrial teachers.
Eight academic teachers.
Two physical education teachers.

II. *Rooms:*

Sixteen in the school building.
Six industrial rooms in other buildings.

III. *Children:*

213 children in the academic department with intelligence quotients above 50 per cent and between six and eighteen years of age.
75 boys in industrial departments, with intelligence quotients from 30 to 50 per cent and between six and eighteen years of age.
99 girls in industrial departments, with intelligence quotients from 30 to 50 per cent and from six to eighteen years of age.

*The Board of Control has been replaced by the Department of Social Security which consists of the Divisions of Employment and Security, Social Welfare, and Public Institutions, as created by the Reorganization Act which was passed by the last legislature. Feeble-minded persons are committed to the guardianship of the Director of Social Welfare, and the School for Feeble-Minded is operated under the supervision of the Director of Public Institutions.

83 boys in vocational shops and dairy with intelligence quotients above 45 per cent and from seventeen to forty years old.

29 girls in vocational departments with intelligence quotients above 45 per cent and from seventeen to forty years old.

The School Department reports to the Case Conference the record of each child as soon as training is completed to determine whether community placement is desirable. Favorable action occurs only if the individual is considered likely to possess all the qualities necessary to maintain himself in whole or in part under local supervision. If approval occurs, the County Welfare Board is so informed, together with a statement of the appearance, physical condition, training and proficiency, habits, and emotional stability of the individual with the recommendation that plans for placement be undertaken. Placement is recommended by the Case Conference if the members approve the plans submitted. The person is discharged from the institution when authorization is received from the Board of Control, and thereafter is under the permanent supervision of County Welfare Board. Ordinarily, a female in the child-bearing years, or a male, irrespective of age, is not paroled unless sterilized.

Group four, consisting of those admitted for sterilization and immediate return to the community, are represented by cases in which one or both mates in a family are sent to us for the purpose of sterilization, upon the recommendation of the County Welfare Board. They return to their own homes after convalescence. A case in this group is that of a man thirty-two years old whose intelligence quotient was 43. He had lived all his life on a farm and had good habits. All the members of his family were subnormal and depended upon him to do most of the work. When his County Welfare Board learned that he had married, steps were taken to have him committed as feeble-minded and a few days after his marriage he agreed to enter our institution immediately to be sterilized and was then paroled to his home. Another one of this group was a mother, thirty-nine years of age, with an intelligence quotient of 59, who was sent to our hospital during the past year to be confined and who had consented to sterilization thereafter. She gave birth to her fifteenth child, of whom all but one were living. It had been determined before she was sent to us that three

of her children were morons, one was dull-normal, and the others had not had a psychometric examination. Five of them were of pre-school age and the attendance of the others at school was intermittent because of the laxity of the parents. The two eldest daughters became illegitimately pregnant at the ages of fifteen and seventeen years respectively, and one of them has been committed as feeble-minded. During the year 1938, twenty-four women, after commitment, were admitted for confinement with the possibility of sterilization if a plan for their return to the community were approved. For seventeen of this group such a procedure is evolving or has been completed. Nine of the twenty-four are unmarried mothers, nine are married and already have families which exhibit degrees of mental defect, while six have been married, and are not living with their husbands—the last child being illegitimate.

The fifth group is made up of girls transferred to us from the State School for Delinquent Girls at Sauk Center. This institution is not one planned for the care of feeble-minded but some are found to be mentally defective after admission and these are committed to the custody of the State Board of Control. However, because of our lack of space, their training is completed at Sauk Center and those considered suitable for placement are sent to us for sterilization. This group will be transferred to an institution for feeble-minded immediately after commitment when sufficient space is provided.

Last August a questionnaire was sent to the County Welfare Boards relative to those on parole from our institution to determine how well they were adjusting to community life. Of 1,190 sent, 906 responses were received, of which 765 referred to females and 141 to males. The data have not been completely tabulated but the reports leave a favorable impression and justify the efforts to return desirable, trained mental defectives to life outside the institution under proper supervision. A study made in Hennepin County March 31, 1939, of individuals on parole from the institution, showed that there were at the time, 102 of 140 females, and 29 of 49 males, employed under the supervision of the County Welfare Board.

Since 1921 our institution has shared with the state in the splendid work done by Dr. F. Kuhlmann as Director of the Division of Examina-

MENTAL DEFECTIVES IN MINNESOTA—ENGBERG

tion and Classification of the State Board of Control. All the mental testing done in our institution has been under his direction and all questionable cases have been referred to him for a recommendation as to disposition. Those determined not to be feeble-minded are discharged as soon as other plans have been made for them. Dr. Kuhlmann has been responsible, also, for the broad testing program conducted in all counties of the state. On March 1, 1939, tests showing intelligence quotients of less than 75 per cent had been given to 25,137 persons on an individual basis since 1923 and, during this period 7,256 committed to state guardianship as feeble-minded. However, on that date there was of record a total of 9,144 mentally defective persons receiving some kind of care, treatment, supervision or training at public expense. They were distributed as follows:

- 2510—in the School for Feeble-Minded.
- 493—in other institutions, committed.
- 1450—satisfactorily adjusted outside but committed.
- 1194—committed, awaiting institutionalization.
- 3497—in special classes. This is an estimate. It is the number of children enrolled in forty cities and towns conducting special classes for subnormal children during this school year 1937-1938. Very few of these are committed as feeble-minded.

ANALYSIS OF DISCHARGES For the Calendar Year 1938

	Males		Females		Total
	Ster.	Not Ster.	Ster.	Not Ster.	
To county supervision after period of institutionalization	12	5	32	8	57
To county supervision after sterilization only	17		35		52

Escapes		11	6	4	21
Deaths		31	1	12	44
Totals	39	87	122	45	293
	126		167		

The total of 9,144 given above does not include any of the 932 patients in the Colony of Epileptics at Cambridge. The majority of these are mentally defective in addition to suffering from epilepsy, and properly increase the known total of mental defectives in the state to about 10,076.

Annual commitments are now in excess of 700 per year, and the waiting list of 1,200 is already so large that from three to five years elapses after commitment before space becomes available at Faribault. This unfortunate condition

will now become noticeably worse until space at another institution is provided, as in the past two years we have been able to increase our capacity to its maximum. This is shown by the record of inmates in the institution as of April 29 as follows: 2,245 in 1934; 2,263 in 1935; 2,274 in 1936; 2,261 in 1937; 2,373 in 1938; and 2,537 in 1939. Hereafter, new admissions will have to be limited, however, to the number discharged from the institution. Those on the waiting lists will be the problems of the local counties and many of them it will be almost impossible to handle in the community, especially the low grade hyperactive, destructive, or untidy children; or those with bad sex habits in families with other children; and the high grade mental defectives with delinquent tendencies. Arrangements are made by the County Welfare Boards for the unmarried to live with families in boarding homes, or in private institutions of various kinds; while some of the married ones, instead, may be supervised in their own homes—sometimes with their children.

The accompanying tables are presented to show the movements of the population at the Faribault Institution for Feeble-Minded in the calendar year 1938.

The above admissions and discharges occurred during a year in which our average daily population was 2,349 (females 1,126; males 1,223)

and is representative of what will probably be the record in the future except for the reduced number of new admissions.

In closing, it is proper to repeat that although state institutions still play a necessary part, they cannot solve the entire problem of the care and treatment of mental defectives. In other words, the solution is not as simple as merely the commitment to an institution. Rather, the problem is so great that we must plan for reasonable control, rather than for complete solution. This requires the combined, coördinated efforts of the local communities, schools, courts, local county welfare boards, institutions, and the state department. It is essential that physicians in local communities recognize the condition when encountered in practice so that they may personally, or through reference to qualified specialists, give proper advice to the patient's family or welfare agencies and also, when necessary, to properly meet the legal requirements for possible commitment. To diagnose and recognize the needs for low grade mental defectives is not difficult, but to do the same for morons requires a thorough knowledge of this group. The failure to recognize all mental defectives presenting social problems and the failure or delay in establishing proper control of them results in great expense, unhappiness, and suffering.

PRESENT-DAY TREATMENT OF UNUNITED FRACTURES OF THE NECK OF THE FEMUR*

MELVIN S. HENDERSON, M.D.
Rochester, Minnesota

UNUNITED fractures of the neck of the femur are more commonly encountered among elderly women than among elderly men. Many of the patients manage to get along well enough to meet the economic and social demands made on people of their age, and if so, surgical measures need not be considered.

Selection of Patients for Surgical Operation

If disability and pain, further complicated by social and economic conditions, make life un-

happy, surgical interference may be deemed advisable. The surgeon, however, must be convinced, first of all, that the patient's life expectancy warrants the time and money to be expended by the patient. The surgeon must be sure, also, that the operative risk as to life, infection and so on, is justifiable. Organic heart disease, such as myocarditis and involvement of the coronary arteries, are distinct contraindications to operation, and obesity, if it is at all marked, is an unfavorable factor. Very rarely should a patient who is more than sixty-five years of age be operated upon for an ununited fracture of the hip.

*From the Section on Orthopedic Surgery, The Mayo Clinic, Rochester, Minnesota.

Pathologic Changes in the Hip

The condition and contour of the head and neck of the femur are of extreme importance if surgical intervention is to be considered, and much is to be learned from careful roentgenologic study. If a great deal of the neck of the femur has been absorbed, and if there is great laxity at the site of fracture, the probabilities are that little, if any, fibrous union is present. An idea as to the degree of laxity can be gained by measuring the distance from the anterior superior spine of the ilium to the internal malleolus: first, while the leg is strongly pulled and, second, while a strong push is exerted upward, with the knee held fully extended, and then noting the difference in measurements. Roentgenograms made while the same forces are exerted confirm whether there is much laxity.

The distinction between fibrous union and true nonunion (pseudarthrosis) is important.

Roentgenologic examination gives much valuable information. The degree of absorption of the femoral neck can be determined if the film is made with the foot held upright, or even rotated a bit medially. If the head of the femur casts a dense shadow, the chances are that it is necrotic; if it appears osteoporotic, the chances are that it is viable. In doubtful cases, it is only on exploration of the joint that the exact condition can be ascertained and, even then, it is not always easy to determine definitely the viability of the head.

Types of Operation

An ununited fracture of the neck of the femur causes disability because of lack of skeletal support; the strain of weight-bearing is borne by ligaments and muscles. In a few unusual cases, in which the patients were younger men, I have seen fibrous union become so firm that they could carry on their activities, even at hard labor. Therefore, the prime object of all surgical procedures is to provide skeletal support if the fibrous union is too weak. Sometimes, by waiting several years, the fibrous union becomes strong enough for the patient to get about with a cane. The question of whether to operate is to be decided by the surgeon and the patient in each individual case; definite rules cannot be laid down.

A number of surgical procedures may be used. Such operations are not common and members of the medical profession at large are not as familiar with them as they are with operations for

more common conditions. The first aim in repairing any fracture, recent or old, is to restore the parts as nearly as possible to their normal anatomic condition and to restore to the part its normal physiologic action. In general, there are three headings under which surgical operations for ununited fractures of the neck of the femur can be discussed: (1) anatomic restitution, which gives the best chance of physiologic recovery, (2) furnishing of skeletal support, with retention of as much motion as possible, and (3) obliteration of all function except weight-bearing, motion being eliminated by arthrodesis. The different operations will be discussed according to this classification.

Anatomic Restitution

Operations under this heading aim to save the head of the femur and induce it to unite either with the neck of the femur or with the remodeled upper end of the femur. Motion of the joint is preserved.

Autogenous Bone Graft.—Use of the autogenous bone graft has been advocated for many years, and, in properly selected cases, has brought about many brilliant results. It should be attempted only by those who possess the necessary advantages as to proper hospital facilities, instruments and skill. It can be performed in one of two ways: by the open method (articular osteosynthesis), or by the closed method (extra-articular osteosynthesis).

The open method demands wide exposure of the joint, careful dissection of all fibrous material from between the fragments and meticulous freshening and fitting together of the surface of the fracture. It is especially suited for younger patients who are in excellent general condition. I have traced sixty-seven of seventy-seven patients in whom an autogenous bone graft was used for an ununited fracture of the neck of the femur. This study covered the period of twenty-six years from July, 1913, to June, 1939, inclusive. It is apparent that these operations are not commonly performed. Bony union was obtained in 69 per cent of cases, whereas in 31 per cent the operation resulted in failure (Fig. 1).

The so-called closed, or blind, method of insertion of the graft has come into prominence in recent years and has the definite advantage that the operation is performed without opening the joint. Therefore, there is much less danger to

the patient from shock and other untoward events. Before this type of operation is undertaken, all shortening must be overcome by either skeletal or skin traction and the roentgenogram

reamer used is a little smaller than the diameter of the fibula. The reamers are threaded on the wire and therefore cannot deviate from the proper direction. The guide wire must be placed deep in

Fig. 1. Bone graft eleven years after insertion for ununited fracture of the neck of the femur (intra-articular osteosynthesis). Firm union; excellent function.

Fig. 2. Solid, bony union with normal function obtained after extra-articular osteosynthesis (fibula). The patient was a woman, sixty-seven years of age, with nonunion of the neck of the femur of one year's duration.

must show that the femoral head and neck are in normal alignment. With this condition of shortening overcome, the bone graft can then be inserted so that, after the operation, it is not subject to any undue stress or strain, the fragments being locked firmly together and the leg put up in abduction so that the position is maintained and the bone graft merely acts to steady it.

Our experience with this method has been encouraging, and I believe that in carefully selected cases it can be used. For this reason, I shall describe the procedure in further detail.

The fibula furnishes excellent material for insertion by the "closed" method, and a full segment of definite length of the bone can be removed, without functional damage, from the middle third of the leg. With the patient on the fracture table, a small, longitudinal incision is made laterally over the trochanter and extends downward for a short distance over the shaft of the femur. A Kirschner wire then is inserted through the trochanter, through the remnant of the femoral neck and well into the head. To be certain that the wire has been properly centered, its position is verified by anteroposterior and lateral roentgenograms. With the wire satisfactorily placed, three cannulated reamers of different sizes are used in series to prepare a channel for reception of the piece of fibula; the last

the head, even penetrating into the acetabulum, or it will loosen and pull out as the reamers are withdrawn. The piece of fibula is slid along the Kirschner wire, and pounded in. One important step in preparing the piece of fibula is the stripping of the muscles and the thorough roughening of the cortex by aid of a chisel, thus producing a roughened and freshened surface and so facilitating the entrance of blood vessels into the graft, furthering its nutrition (Fig. 2).

If the condition is true pseudarthrosis, that is, if there is no fibrous union, this method of blind insertion of the graft, without freshening of the fragments, will probably fail. It is known that the driving of an autogenous bone graft across joint surfaces will not lead to ankylosis because the bone graft will not receive any nourishment where it traverses the joint space and will weaken and fracture there.

Metal Nail for Fixation.—Another method is to open the joint, freshen the surfaces of the fragments and hold them in apposition by pinning them together with a Smith-Petersen nail. There have been no reports, so far as I know, of any sizeable series of patients treated by this method. However, it is reasonable to assume that with good technic and careful fitting of the fragments, good results might be the rule, if the femoral head is not necrotic.

Brackett Operation.—The Brackett operation is a sound surgical procedure. It consists of complete exposure of the hip joint by lifting upward the trochanter and its attached muscles, removing any fibrous tissue between the fragments, freshening of the fracture surface of the head and remodeling of the upper end of the femur, which may mean entire removal of the remnant of the femoral neck in order to fit it accurately to the head. The trochanter, with its attached muscle that has been reflected upward, is brought down and fastened at a lower level on the shaft of the femur. This step is important because it restores normal tension of the muscles. The operation is best suited to younger individuals and the head of the femur must be viable (Fig. 3). It is a major surgical procedure and should not be undertaken if patients are old or debilitated.

Care Following Operations for Anatomic Restitution

Following operations of the types mentioned, namely, bone grafting, nailing or the Brackett operation, it is essential that firm and adequate postoperative fixation be maintained a sufficient length of time for bony union to develop. This cannot be expected to occur in less than three months. Such prolonged fixation may be a trial and burden for elderly and weak persons and entails long confinement in the hospital. The stiff knees so often encountered following prolonged fixation are further complications that greatly retard convalescence.

Reconstruction Procedures, the Objects of Which Are to Furnish Skeletal Support

If, because of a necrotic femoral head, advanced age, and so on, the more nearly ideal procedures that aim at anatomic restitution cannot be carried out, the aim has to be merely to restore skeletal support and to save as much motion as possible.

Whitman Operation.—Royal Whitman, famed for his advocacy of the closed treatment of fresh fractures of the neck of the femur, later described a reconstruction operation since known by his name, for nonunion of the neck of the femur. The essential points of the operation are removal of the head of the femur, remodeling of the upper end of the femur, which is then placed in the acetabulum, and moving the trochanter, with its attached muscles, to a lower level on the shaft of the femur (Fig. 4).

Colonna Operation.—Paul Colonna has developed a procedure somewhat similar to that of Whitman in that the head of the femur is removed and also the remnant of the neck. Colonna carefully strips the trochanteric muscles from the trochanter, gathering them together by aid of a purse-string suture. The trochanter is placed in the acetabulum, with the hip in abduction, and the reflected muscles are fastened, by aid of the purse-string suture, through a hole bored through the shaft at a lower level, thus keeping the gluteal muscles under normal tension (Fig. 5).

Albee Operation.—Albee has advocated a reconstruction operation wherein the head of the femur is removed also, but, in addition, perpendicular osteotomy, from downward, at the junction of the neck and the trochanter, is performed and the outer fragment, with the trochanter and its muscles, is pried outward. He then puts the upper end of the femur in the acetabulum and, in order to hold the trochanter and its muscles outward, inserts in the cleft left by the osteotomy such an amount of the head of the femur as is necessary to maintain the fragment in its lateral position. The object of this last step is to provide leverage for the trochanteric muscles.

Care Following the Whitman, Colonna and Albee Operations

Postoperative fixation is extremely important for the success of any one of these reconstruction procedures. The hip must be maintained in a well abducted position long enough to insure reattachment of the muscles to the femur, so that they can institute motion of the reconstructed joint when the cast is removed. This position should be held from three to four weeks, but flexion of the hip may be passively carried out and thus the knee exercised as early as two weeks after operation. The institution of motion of the knee as early as possible is greatly to be desired and definitely shortens convalescence. These operations give bony stability but many of the patients are forced to resort to the aid of a cane or crutch in walking any great distance. However, on the whole, the results are satisfactory and well worthwhile.

Other Procedures that Furnish Skeletal Support

High Osteotomy.—Of recent years, it has been argued that if the line of weight-bearing could be altered and the lower fragment brought well

inward beneath the head, the shearing force, when weight-bearing is attempted, will be abolished. To this end, the high osteotomy, effected really between the greater and lesser trochanters,

is durable and in the main unsuitable for elderly patients, and, second, it is not easy really to obtain bony ankylosis in the elderly. It would seem that pain is the chief indication for its use, but usual-

Fig. 3. Result ten months after Brackett operation.

Fig. 4. Result three years after Whitman reconstruction operation.

Fig. 5. Skeletal weight-bearing accomplished by Colonna operation.

has been advocated strongly by McMurray of Liverpool. He has reported that function has been much improved and he has stated further that in many cases healing has progressed to bony union after this new line of weight-bearing has become established. I have had too little experience with this operation to express an opinion. More definite information no doubt will be at hand shortly, for the operation is being performed with increasing frequency in a number of clinics in America.

Low Osteotomy.—Lorenz, of Vienna, advocated low osteotomy, effected below the lesser trochanter, and placing of the upper end of the lower fragment in the acetabulum. He recommended this operation for irreducible congenital dislocation of the hip. Somewhat the same procedure has been advocated for ununited fracture of the hip. In such an operation the upper end of the lower fragment is placed just beneath the femoral head. I have had no experience with it.

Arthrodesis for Stability

If none of the aforementioned procedures is deemed advisable, if the patient is incapacitated seriously and perhaps is suffering with much pain, arthrodesis of the hip joint should be considered. However, a stiff hip is an awkward affair if the patient is elderly. Arthrodesis has been resorted to rarely in America for this condition, first, because it is a major surgical proce-

ly this can be controlled by limitation of activities.

Summary

Ununited fractures of the neck of the femur can be treated surgically if the patient is in good general condition and has an expectancy of life that warrants surgical measures.

The types of operation can be grouped under three headings: (1) those that aim at securing anatomic restitution, with bony union of the fragments, (2) those that aim, by the so-called reconstruction operations, to furnish skeletal support and still to allow motion, and (3) arthrodesis that aims to furnish only skeletal support with complete loss of motion.

No rules can be laid down as to what patients should be subjected to surgical measures or as to what type of operation should be employed. Each case must be considered individually and the decision made on the basis of the findings.

SURGERY OF COMMON AND HEPATIC DUCT CALCULI*

HAMLIN MATTSON, M.D., M.S. (Surg.), F.A.C.S.

Minneapolis, Minnesota

BILIARY surgery, like modern surgery in general, is of such relatively recent development that it is little wonder the biliary ducts have been slow to receive the attention they merit. The origin of attention is so recent as to be within the life span of some to whom today the problem is of everyday occurrence.

It was June 15, 1882, when Carl Langenbuch of Germany performed the first cholecystectomy. In 1887, Justus Ohage, Sr., once president of the Minnesota State Medical Association, first performed cholecystectomy in America. Although cholecystectomy is among the most frequently performed of abdominal procedures and usually is accomplished without difficulty, it may be one of the most difficult problems. When the ducts contain calculi the situation becomes more serious for the patient and technically more difficult for the surgeon.

Frequency of Ductal Calculi

The most common cause of recurrence of colic following cholecystectomy is choledocholithiasis. Lithiasis is the most common cause for secondary operations on the biliary tract, with stricture next in frequency. When cholecystectomy is performed without giving attention to the ductal system, calculi are being left in the ducts in from 10 to 20 per cent of the cases. Wilkie¹⁵ reported removing one or more calculi from the common duct in 18 per cent of 257 cases of cholelithiasis. Ravdin,¹¹ in a study of ninety-five cases of cholelithiasis, found ductal calculi in over 14 per cent. Lahey⁶ has estimated the average incidence at 20 per cent. Cutler² recently reviewed 397 operations for cholelithiasis performed between 1934 and 1938 at Peter Bent Brigham hospital. Common duct stones were found in 18.6 per cent of all cases, in 51 per cent of common ducts opened. There was no mortality in seventy-one cases, where the duct was opened and no stones were found.

The frequency with which calculi are found in the common or hepatic ducts, therefore, seems to be in direct proportion to the diligence and com-

petence of the surgical attention to the ductal system. Obviously, careful examination of the common duct should be a routine consideration in every operation on the biliary tract.

The first step in the prevention of recurrent colics following cholecystectomy, therefore, is the recognition and management of choledocholithiasis *at the original procedure*. The anatomy then is defined more clearly and the tissues dissected more easily. The problems in secondary operations on the common duct, often in anemic and jaundiced patients, are much more formidable. As shown in many studies, not only the common duct but the whole biliary tree and the interrelated organs must be considered in surgical treatment of the biliary system.^{5,7}

The following study is based on personal experience and a review of the surgery of ductal calculi at the Minneapolis General Hospital from January 1, 1928, to January 1, 1938, when 283 cholecystectomies for cholelithiasis were performed. The common duct was opened twenty-nine times and calculi were removed from the common and hepatic ducts in fourteen cases. The common duct was opened more freely in the latter half of the decade.

Diagnosis of Choledocholithiasis

It is recognized today that calculi may lie dormant in the ductal system for years. Symptoms follow sooner or later in most cases. Symptoms arising from common or hepatic duct calculi are those of cholecystic disease plus jaundice. If symptoms persist following a typical attack of biliary colic, disturbance in the ducts should be suspected.

Colic is the most common and characteristic symptom of choledocholithiasis. In this series of common duct calculi, colicky pain was present in 85 per cent of the cases. In 14 per cent the pain was dull and boring. In the largest recorded series,⁴ pain was absent entirely in 2.4 per cent of cases.

The most frequent cause of jaundice of all types is common duct calculus. Jaundice was present in 85 per cent of the patients in this series. Chills and fever were present in one out of

*From the Department of Surgery, University of Minnesota Medical School.

three of the patients. Other gastro-intestinal disturbances were present in most cases. Nausea and vomiting were present in eleven of the fourteen cases in which calculi were removed from the common duct.

No one is infallible in the differential diagnosis of jaundice. A gallbladder may be distended in cases of choledocholithiasis and contracted in malignant obstruction. Colic may occur in cases of carcinoma and not infrequently is absent in cases of stone. Pylorospasm may be the only symptom of a common duct calculus. But a guess is a poor peg when the thread of a human life hangs on it. Exploration is therefore indicated in all cases of probable ductal obstruction where such examination can be carried out within reasonable risk.

Watson^{13,14} has been very successful in distinguishing calculous, cancerous, parenchymal, and hemolytic forms of jaundice by determining the excretion of urobilinogen in urine and feces.

If common duct obstruction is complete, the serum bilirubin will become fixed at from 20 to 30 milligrams for each 100 c.c. of blood, with the icterus index usually between 150 and 200 units. The jaundice of common duct calculi, however, is almost always intermittent. The intermittency of symptoms provides an excellent diagnostic clue. If a Rehfuß tube is passed three or four times, bile can almost always be recovered if obstruction is due to calculus.

Surgical Preparation

Operation is best performed when the serum bilirubin is normal, or tends to be on the decline, or is not increasing; and best not performed until after attempts to reduce prothrombin time. If the jaundice does not recede within two weeks, the common duct should be explored usually. Patients with deep jaundice of short duration are better risks than patients with less jaundice of long duration. Blood transfusions are helpful in reducing the incidence of hemorrhage and improving the patient's resistance. Of great value is the restoration of glycogen reserve in the liver.⁸

Increasing use of vitamin K substances and bile salts in cases with prothrombin deficiency has decreased considerably the need for blood transfusions in the control of the bleeding tendency.

Methods used for measuring bleeding tendency in a jaundiced patient still are far from perfect.

Quick's¹⁰ method for determining thromboplastic activity has proven useful clinically. Simpler and more practical for bedside use, especially in smaller hospitals, is a test recently developed by Ziffren and associates.^{16*}

Within recent months the structure of the vitamin K (from alfalfa) molecule has been found to be 2 ethyl-3 phytyl-1, 4-naphthaquinone and the compound has been synthesized. Other quinones have been found to have vitamin K activity.

At the present time it seems best to determine prothrombin clotting time in each patient with jaundice and give concentrates of vitamin K and bile salts prophylactically in each such patient before operation. If the prothrombin time is prolonged such concentrates and bile salts should be given until the prothrombin time is within normal limits. After operation prothrombin values should be determined daily for three or four days, then every other day until the ninth or tenth postoperative day. When prothrombin deficiency is found, vitamin K concentrates and bile salts should be given. Where prothrombin deficiency is shown before operation it is wise to give such treatment postoperatively regardless of prothrombin values. When marked hepatitis is found at operation it seems wise to give vitamin K and bile salts postoperatively regardless of prothrombin values. Intravenous injections of glucose and blood transfusions should not be ignored in combating the bleeding tendency.

Indications for Opening Common Duct

When should the common duct be opened? Routine choledochotomy has a few advocates; but such a policy appears to be too radical. Puestow and Morrison⁹ measured the common duct in 527 routine necropsies showing no biliary tract disease and found the average circumference in adults to be 12.1 millimeters. In other words, in a person of average weight, the common duct is

*One-tenth cubic centimeter thromboplastin is placed in a three cubic centimeter tube and freshly drawn blood added up to the one cubic centimeter mark. The tube is inverted once and tilted gently every few seconds and the clotting time observed. This is repeated in a normal individual.

$$\text{Clotting activity (In percentage of normal)} = \frac{\text{Clotting time of normal}}{\text{Clotting time of unknown}} \times 100$$

The above has been found to agree within 15 per cent with quantitative tests. With prothrombin below 30 to 50 per cent, bleeding tendency appears. Above this level blood clots at a normal rate (six to ten minutes).

To prepare thromboplastin, extract 10 grams of ground brain or lung (ox or rabbit) two hours with 10 cubic centimeters saline, strain and preserve in an icebox. If normal exceeds sixty seconds the thromboplastin should be rejected; if less than twenty-five seconds thromboplastin should be diluted with saline.

about the size of a goose quill. Routine exploration would prolong the operation, increase the operative risk and increase the frequency of the second most common cause of secondary biliary operations—stricture of the duct from operative injury. Calculus or other obstruction is followed practically always by dilatation of the duct or thickening or discoloration of its wall.

On the whole, according to present knowledge, it would be wise to open the common duct when:

1. *A calculus is felt or suspected.* Palpation of the common duct should be as much a routine in cholecystectomy as palpation of the gallbladder itself. It is much more difficult to palpate smaller stones which may not be giving symptoms but which may increase in size and cause difficulty later. The common duct is palpated with the index and second fingers of the left hand in the epiploic foramen and the thumb above the hepatico-duodenal ligament. Often it is best to catch the stone between the thumb and fingers and open the duct directly upon it. A floating stone may be milked up from the lower duct and fixed in a favorable position for removal. On occasion, lymph nodes in the gastrohepatic omentum and localized indurated areas in the pancreas cannot be distinguished from calculi by palpation.

2. *When the duct is definitely dilated or thickened.* The enlargement should be beyond the compensatory dilatation accompanying autocholecystectomy.

3. *In the presence of cholangitis or pancreatitis.* Drainage in such instances is indicated in any event. About one in ten common duct stones are in the ampulla. In two out of three patients, the common duct is surrounded completely by pancreatic tissue in the terminal portion.

4. *In the presence of a history of chills, fever, and jaundice.*

5. *In the presence of recurrent or intractable symptoms following biliary operations of any kind.*

Major influencing factors may be: (a) a history of pronounced involuntary vomiting where a stone is not found impacted in the cystic duct; (b) markedly thickened or contracted gallbladder; (c) the presence of small stones in the gallbladder together with a dilated cystic duct; and (d) a history of severe and persistent colic.

Technic of Common Duct Operation

Adequate exposure of the ducts is essential. In the presence of cholelithiasis the gallbladder should not be removed until the ductal system has been examined properly and the organ should not be removed without assurance that the common and hepatic ducts are free of calculi. Exploration through the cystic duct stump is rarely if ever feasible. In the presence of jaundice associated with infection of the biliary tree, it may be wiser in rare instances to drain rather than remove the gallbladder.

A commonly used and practical incision is started high in the angle between the costal cartilage and the xiphoid and extends down not more than 1.5 or 2 cm. from the midline to a point opposite or a little below the umbilicus. The right rectus muscle is split or retracted. The posterior aponeurosis, peritoneum and the nerves in the lower third of the incision are preserved. The incision is from 4 to 5 cm. longer through the fat and subcutaneous tissues than through the fascia. There should be no hesitancy to extend the incision to obtain good exposure.

It is possible to remove calculi in practically all instances by the supraduodenal approach (Kummel's operation, Thornton's operation). The retroduodenal approach (Hassler's operation) is mainly of historical interest now. In very rare instances it may be necessary to open the duodenum at a point 8 cm. distal to the pyloric vein and free the stone either by cutting the sphincter (McBurney's operation) or by transduodenal choledochotomy (Kocher's operation).

By the supraduodenal approach the peritoneum covering the common duct is split parallel to it. The common duct is exposed by blunt dissection. A small artery along the ventral surface of the duct may cause troublesome bleeding. Occasionally the portal vein will lie in the lateral and anterior portion of the hepatico-duodenal ligament usually occupied by the common duct. Because of this it is safe to aspirate with a needle before opening what seems to be the common duct. Unless opened directly upon a stone, the common duct is incised longitudinally about a centimeter below the entrance of the cystic duct. It often is wise to aspirate what appears to be the common duct for bile before incision is made. The duct on either side of the incision may be fixed by two Allis forceps or two fine silk ligatures may be placed.

Insertion of 3 mm. to 8 mm. scoops and a forceps, as well as manual palpation on the inserted scoops may aid in locating a calculus, especially in the ampulla. As many calculi as pos-

Drainage of Common Duct

Operative procedures on the common duct rarely fail to require drainage, with this need continuing up to weeks, months and in some in-

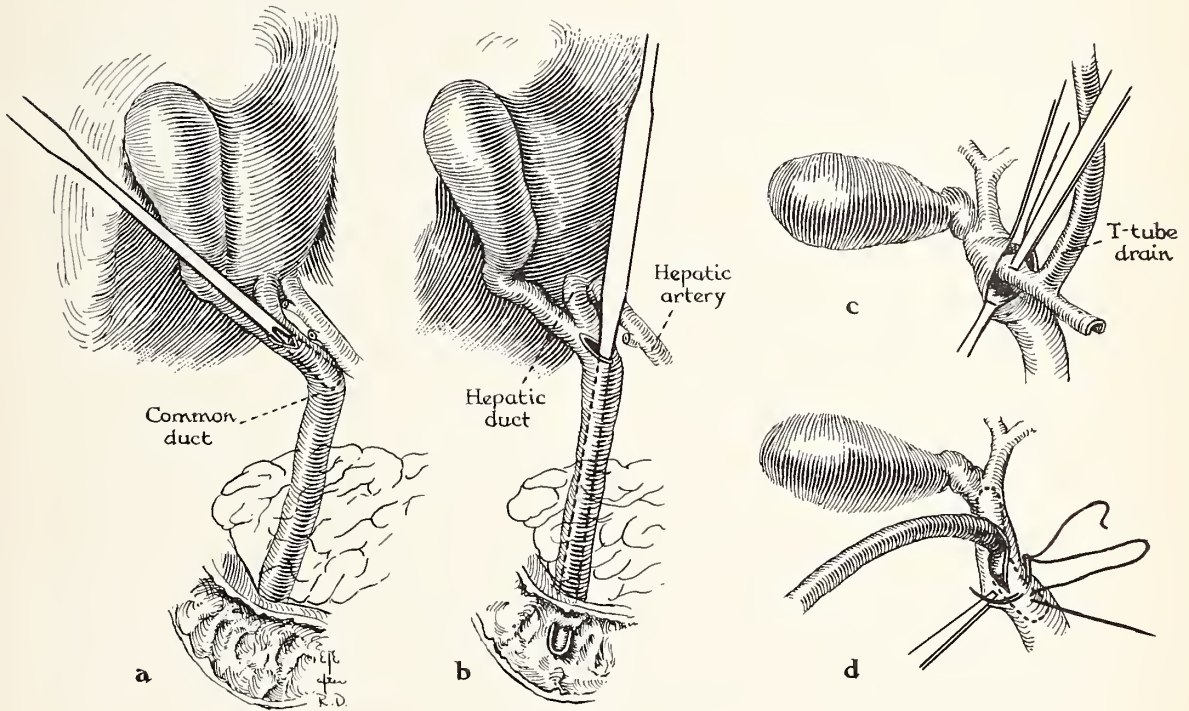

Fig. 1.

sible may be scooped out. Sometimes stones in the hepatic ducts can be flushed down by physiological saline injected into a catheter. Suction may assist delivery of certain stones. Calculi in the substance of the liver are reported rarely, although they must be more frequent than hitherto suspected. Crump¹ studied 1,000 consecutive autopsies in 1931 and found hepatic duct stones in 13 per cent. In a large duct, and when feasible, the finger is the best exploring instrument.

The choledochal sphincter may be dilated gently by graduated rounded scoops or catheters. But caution should be exercised in dilating the sphincter. Recent studies in dogs and man¹⁷ showed traumatic reaction with subsequent spasm and scarring of the sphincter following marked dilatation. Use of catheters insures gentleness in the ampullary and sphincter region. A small catheter (10 F) may be passed through the papilla and saline injected to note filling of the duodenum, indicating the duct is open. Then a larger catheter (16 F) may be passed.

stances years. Three types of drainage tubes may be used: (1) T-tube, (2) L-shaped rubber catheter (Horgan³), or (3) an ordinary urethral catheter. The two limbs of the T-tube crosspiece are cut to about 2.5 centimeters before insertion. It is possible to injure the duct during removal of the T-tube. Cutting a window opposite the vertical limb or removing the bottom half of the crosspiece will reduce such risk. Instances are known of the transverse portion of the tube's having broken off and remained in the common duct. A straight catheter is not adaptable for prolonged periods of drainage. The common duct may be closed with two layers of 00000 chromic catgut on an intestinal needle.

A T-tube can be left in as long as necessary and removed easily, often without anesthesia. Intravenous pentothal or evipal soluble anesthesia may be used if necessary. With a T-tube the flow of bile can be controlled better by clamping, fluids for feeding can be given, the ducts irrigated and roentgenograms made of the biliary

tree. Ten to 20 cubic centimeters hippuran is a good contrast medium for cholelithograms.

Often the drainage tube can be removed during the second or third week following operation. With deep jaundice and marked cholangitis and hepatitis or pancreatitis, prolonged drainage is indicated. The tube should not be removed until the cholangiogram shows the biliary tree has approached normal structure, that no filling defects suggestive of stones are present, and that the opaque medium empties readily into the duodenum (within ten minutes). There should be no discomfort to the patient and no drainage around the tube when it is clamped before removing it. It may be several months before such requirements are met. Tubes have been known to be in place many years without difficulty. Wangenstein¹² has observed a patient carrying common duct catheters for six years.

Summary

A study of surgery of common duct stones encountered in 283 cholecystectomies is presented together with the observations from personal experience and the work of others. Common duct calculi occur in one to two of ten cases of cholecystitis with stones and practically always are best taken care of at the time of the original cholecystectomy. Opening a duct and finding no

calculi should not increase the mortality rate. Indications for opening the common duct are given.

FULMINATING ULCERATIVE COLITIS

A Critical Analysis of Twenty Cases

CARL P. SCHLICKE, M.D.,* and J. ARNOLD BARGEN, M.D.

Rochester, Minnesota

THE course and progress of various forms of ulcerative colitis have been depicted as insidious, severe and fulminating.^{1,2} It has been pointed out that in some cases in which the "fulminating state with progressive severity" exists, death may be the sequel of a most distressing and irresistible illness.

In recent months, many patients with chronic ulcerative colitis have been observed during fulminating exacerbations of their illness. These are patients in whom the disease is definitely not tuberculous or amebic in origin, but in whom

it is of the varieties of types 1, 2, 3, 6 or 7.³ It was felt that a critical study of a number of these cases might be of value.

Approximately 300 cases of chronic ulcerative colitis have been seen at The Mayo Clinic during each of the last three years. In those years between five and seven patients have died from this disease annually. The cases selected for study represent the last ten patients with a fatal outcome of chronic ulcerative colitis prior to August 1, 1939. As a basis for comparison, an analysis was made of ten similar cases of fulminating ulcerative colitis in which the patient recovered. This investigation represents an at-

*Fellow in Surgery (Schlicke), The Mayo Foundation, and from the Division of Medicine (Bargen), The Mayo Clinic, Rochester, Minnesota.

tempt to make a critical analysis of the factors contributing toward the mortality in these cases and of the value of our therapeutic efforts, together with an attempt to improve our management of similar cases in the future.

General Data

The ages of the patients in the fatal group ranged between five and seventy-two years, the majority being in the third and fourth decades of life. The ages in the group which recovered ranged between fourteen and forty-two years, the majority being in the third decade. There were four men and six women in the fatal group, while in the group which recovered there were five of each sex. It may be of some interest that nine of the twenty patients were of the Jewish race, five of whom died and four recovered. The patients came from varied walks of life and scattered locations. Most of the patients had enjoyed good general health prior to the onset of the colitis. One of the patients in the fatal group had had attacks of biliary colic, one had had a renal calculus and one had had a duodenal ulcer. In the group which recovered one of the patients had rheumatic endocarditis.

Duration of Illness

There was no correlation between the duration of the illness and the outcome. In the fatal group, the shortest duration of symptoms was seven weeks. Three patients had had their symptoms for less than a year. In the remainder the duration ranged between two and six years. In the group which recovered three of the patients had had their symptoms for less than a year. In the remainder, the duration ranged between one and eight years.

Onset of Illness

The onset of the disease was insidious in five of the fatal cases and in seven of the nonfatal cases. In the remainder of the cases the onset was severe. In all cases in which the symptoms had been present for more than five months before admission, they were intermittent. In the fatal group, in six of the cases the disease became fulminating two to three months before admission to the hospital. In the remaining four, the disease became fulminating while the patient was in the hospital under treatment. In the group which recovered, the disease became

fulminating in eight of the cases during the month preceding admission, while in the remaining two, this change occurred during the patients' stay in the hospital.

Predisposing Factors

In five of the cases in the fatal group, the onset of the attack of colitis from which the patient died was associated with a period of undue nervous stress. In one case an exacerbation followed a dental extraction. In two cases an upper respiratory infection preceded the relapse. In the group which recovered, three of the patients had upper respiratory infections prior to their "flare-ups." Practically all of the patients presented one striking characteristic, regardless of their age or sex, namely, a tense, high-strung, nervous temperament, in most cases associated with a strong tendency toward uncoöperativeness.

Type of Chronic Ulcerative Colitis and Extent of Disease

Only five of the cases of the fatal group were definitely of the streptococcal variety, which we have designated as type 1. The other five were of type 3,³ a nondescript form of ulcerative colitis with irregular proctoscopic, roentgenologic and clinical pictures and one in which the causation is not clear.

At the time of admission, roentgenologic study revealed involvement of the rectum and sigmoid alone in one case in the fatal group. In one case the disease process extended as far as the splenic flexure and in one case as far as the hepatic flexure. The entire colon was involved in two cases. In one case no involvement was demonstrable until the disease had progressed to such a degree that further studies could not be made with safety. Four of the patients were too ill to undergo roentgenologic examination. At necropsy there was involvement of the entire large intestine in all cases.

In the group which recovered, eight cases were of type 1 and two were of type 3. In one case the rectum and sigmoid alone were involved when the patient was first examined. The disease process extended as high as the splenic flexure in one case. In seven cases the entire colon was diseased, while in another case the entire colon and the terminal ileum were also involved.

Proctoscopic examination showed active dis-

ease of the bowel wall in all cases of both groups.

Bacteriologic Studies

In the fatal group, the streptococcus of colitis (Bargen¹) was isolated from the stools in only two cases. Streptococcus faecalis and Streptococcus zymogenes were found in one case. The stools in the remaining cases revealed no unusual bacteria. Blood cultures made in four cases failed to grow bacteria. Serologic agglutinations for typhoid fever, paratyphoid fever and paradysentery were negative in four of the five cases in which these tests were performed. However, in the fifth, a test for Shigella paradysenteriae (Flexner) was reported positive (1-640) but the organisms were absent from the stools in repeated cultures.

In the group which recovered, the streptococcus of colitis (Bargen¹) was isolated from the stools in nine cases. One of these stool specimens also was found to contain Salmonella enteritidis. Blood cultures were made in five cases but no bacteria grew. The results of the serologic agglutination tests for typhoid fever, paratyphoid fever and paradysentery performed in three cases were reported negative.

It is of interest that one of the patients in each group had undergone treatment for amebiasis prior to admission. One patient in the fatal group had been treated for bacillary dysentery and one in the group which recovered had been treated for paratyphoid fever without improvement before admission.

Blood Picture

All patients, except one in the fatal group, showed moderate to severe anemia on admission. Leukocyte counts were for the most part slightly elevated but in only two cases did they exceed 15,000 in each cubic millimeter of blood on admission. No correlation was apparent between the leukocyte count and the severity of the disease. Differential counts showed nothing characteristic but study of the smears revealed a toxic blood picture as indicated by a reversal of the normal filament-nonfilament ratio. The sedimentation rate was elevated in all cases. In three of the cases in which bleeding was a prominent feature, prothrombin deficiency was demonstrated. In each of these cases bleeding ceased

and the prothrombin values approached normal following administration of vitamin K.

Course

The clinical picture and progress of these patients during their stay in the hospital made possible the recognition of two distinct groups. Patients whose symptoms were in the main those produced by a severe thrombo-ulcerative process in the wall of the large bowel composed the first group. These patients had high fever, toxemia, dysentery, hemorrhages, signs of peritoneal irritation and sometimes even actual perforation of the bowel wall. The second group was composed of patients whose predominant symptoms were secondary to the changes in the bowel wall. These were the patients with marked deficiency states, characterized by severe anemia, emaciation, low serum protein, edema and ascites, and in whom fever and toxemia were less prominent features.

Among the patients who died, seven fell into the first group and three into the second. Among the patients who survived, seven fell into the first group and two into the second. One of the survivors began in the first group, but following ileostomy his symptoms became predominantly those of the second group. In general, if the disease process continued at a fulminating level for more than five weeks, signs of deficiency were found to appear.

Complications

These were more common and of a more severe nature in the fatal group than in the non-fatal group. Perforation was the most serious complication and one of the most common in the fatal group. The development of jaundice was an infrequent and inauspicious occurrence. From a prognostic standpoint the development of severe edema seemed to be a discouraging sign. Table 1 indicates the incidence of complications.

Cause of Death

Among the patients who died, peritonitis was the cause of death in five cases. One patient with femoral phlebitis died from pulmonary embolism. Overwhelming toxemia was the cause of death in two cases. The seventy-two-year-old patient died of coronary occlusion. In one case, the cause of death was thought to be acute yellow atrophy of the liver.

TABLE I. INCIDENCE OF COMPLICATIONS IN
FULMINATING THROMBO-ULCERATIVE
COLITIS

Complication	Occurrence among ten patients who died	Occurrence among ten patients who survived
Perforation; peritonitis	6	1
Hemorrhage	2	1
Perianal abscess; fistula	2	6
Polyps	3	2
Contraction; stricture	4	7
Carcinoma	1	0
Jaundice	3	0
Arthritis	0	2
Neuritis	0	1
Otitis media, acute	1	0
Stomatitis; pharyngitis	4	2
Parotitis	1	0
Urinary tract infection	1	0
Cutaneous lesions	0	3
Abscesses (other than perianal)	1	0
Phlebitis	1	1
Edema; ascites	8	3
Total	38	29

Treatment

The treatment of all patients was carried out along the same general lines. When their condition permitted they received a low residue diet, rich in proteins and vitamins. In the presence of peritoneal irritation or impending perforation, feedings were stopped and fluid, nourishment and medications were given parenterally. Vitamin concentrates were supplied liberally.

Antistreptococcic serum (Bargen¹) was administered intramuscularly to eight of the patients who died but only three received what we have considered an amount having therapeutic effect. Two of these patients received only a few isolated injections before death. Small doses of this serum were administered intravenously to three other patients in this group. All of the patients who recovered received an adequate

course of serum therapy. Three of them also were given serum by intravenous injection and one of them received several large doses of antidyenteric serum by this route.

All but one of the patients who survived received colitis streptococcus (Bargen¹) vaccine before discharge. Only two of the patients who died had the benefit of this form of therapy.

Eight of the patients who died received courses of treatment with sulfanilamide or neoprontosil, most of them in amounts which have been of value in the milder cases. Only three of the patients who recovered received these drugs.

Ileostomy was performed on two of the patients in the fatal group and on one of the patients who survived.

Other forms of therapy included blood transfusions, liver extracts, 100 per cent oxygen, courses of emetine, atabrin, various arsenical preparations, histidine hydrochloride and glycine. Sedatives and symptomatic treatment were administered as indicated.

Among the patients who died, four were extremely ill on admission and followed a steady downhill course in spite of everything that was done. One patient seemed to be benefited by therapy but succumbed to a heart attack. The remaining five patients, comparatively speaking, were only moderately ill at the time of admission, yet each of them took an unexpected turn for the worse while under treatment. In one case, an upper respiratory infection seemed to be the precipitating factor. A second was a case of type 3 in which lesions were not noted at the time of the first proctoscopic examination but in which severe ulcerative disease was noted at a second examination two weeks later. In two cases, the cause of the exacerbation was not apparent but the subsequent development of jaundice and coma indicated severe liver damage. In the fifth case, no explanation was at hand.

Among the patients who survived, a single factor to which the credit could be given for the improvement which took place was not apparent. In one, a dramatic response seemed to result from intravenously administered anticolitis serum and in another from the use of 100 per cent oxygen. In another, emetine hydrochloride seemed to alter the course of events. Autogenous vaccine, carbarsone, antidyenteric serum and anticolitis serum, each in its turn, seemed to be the deciding factor. The relief of anasarca by salyr-

gan was followed by prompt general improvement in one case. Surveying the group as a whole, it is apparent that the important feature in the management of these cases was the institution of a well balanced program along the lines outlined at the beginning of this section. Rest, diet, sera and vaccines, neoprontosil and symptomatic measures combined to produce a salutary effect which does not seem to have been achieved by any one measure alone.

Sulfanilamide and neoprontosil represent the latest addition to the therapy of ulcerative colitis. Many patients suffering from chronic ulcerative colitis, especially of the streptococcal and of the "insidious" to "severe" variety, derive unquestionable benefits from the administration of these drugs. However, the institution of this type of treatment often is attended by a transient increase in the number of daily bowel movements, with malaise, nausea and sometimes slight hyperpyrexia. One wonders whether more severe reactions, the "unexplained exacerbations" in the hospital, may not in some cases have been related to the use of sulfamido preparations. In four of the cases herein discussed exacerbations developed following courses of neoprontosil. All of the patients who became jaundiced had received sulfanilamide derivatives. The exact rôle which sulfamido drugs played in the production of these undesirable reactions is difficult to determine, but their occurrence should serve as a warning that the sulfamido group of drugs should be used with caution in the treatment of "chronic ulcerative colitis," particularly of the "fulminating" type.

Summary

A study of ten fatal cases of fulminating thrombo-ulcerative colitis and other severe ulcerative colitis and of ten cases in which the patient recovered has been made. Most of the patients were in the third or fourth decade of life. Nine of the twenty patients were Jews.

The severity of the disease and the outcome bore no relation to the duration of the symptoms,

the mode of onset, the type or extent of involvement of the colon at the time of admission or to the blood picture. The similarity in the course of the two groups of cases is emphasized by the fact that in each group there were seven cases with severe sepsis and two or three with secondary deficiency states.

Streptococci of colitis (Bargen¹) were recovered from the stools in all but one of the cases in which the patient survived but in only two of the cases in which the patient died.

In most cases the clinical picture and course were produced or, at least, influenced by the severity of the infective process but in a certain number a secondary deficiency state was the predominant feature.

Perforation, jaundice and edema were the most serious complications from the standpoint of prognosis. Perforation and peritonitis were the most common causes of death.

No one drug or procedure is curative in "chronic ulcerative colitis" of this fulminating variety. A well planned program, including the use of serums and vaccine and embracing dietary and medicinal aids, seems to be the best form of treatment. It is important to point out that each of the ten patients who survived received what we considered an adequate course of serum. Few of the ten who died received amounts of serum worthy of comment. Nine of the patients who survived received anticolitis vaccine as well. Only two of the patients who died received the vaccine.

The use of sulfanilamide and neoprontosil in the treatment of chronic ulcerative colitis is still in a trial stage. Although of proved value in many cases of this disease, its use is not entirely unattended by danger, especially in cases of the fulminating variety.

The early symptoms of renal tuberculosis are not appreciated, and genito-urinary tuberculosis is regarded as a disease by itself and not as a manifestation of a generalized tuberculous condition. As a result, adequate convalescence and expert after-care are not insisted upon. Sanatorium treatment and continued supervision after operation or local treatment will favorably influence the general prognosis. J. Carver, M.D., *Tubercle*, April, 1939.

HISTORY OF MEDICINE IN MINNESOTA

HISTORY OF MEDICINE IN WINONA COUNTY

(Continued from April issue)

In July of the year of its incorporation, the Winona County Medical Society adopted a regulative fee table and passed resolutions on such matters as interest on unpaid accounts and reduced fees for the poor. Dr. Sheardown was president during the year 1870 and Dr. Cole in 1871. By that time the organization was strengthened and special semi-monthly meetings were held for the discussion of questions such as "The Use of Sulphuric Ether in Obstetrics," "The Use of Hydrate of Chloral," and other topics of interest to the profession. At another meeting, Dr. McGaughey read a paper on the "Purity and Proper Preparation of Medicine," after which a discussion of the merits of different manufacturers and of the city druggists took place.

Another essay by Dr. McGaughey was read at a meeting in 1874 on "Cholera Infantum" in which, aside from the medical treatment, he dwelt emphatically upon importance of utmost cleanliness in the entire surroundings. At the same meeting, Dr. Staples presented an interesting case of congenital deformity which evoked much discussion.

As early as the year 1872 a preparatory medical school was organized in Winona City. It proposed to give preparation for admission into medical colleges. Students were divided into two classes of which the first included those who had not attended college lectures. These received instruction in the fundamental branches. The second group, comprising those who had attended one course of lectures, received instruction in the advanced branches. The school had recitation and dissection rooms and an anatomical and pathological museum. Drs. Franklin Staples, J. B. McGaughey, James M. Cole, D. A. Stewart, and A. P. Gilmore composed the original board of instructors. During the decade or more of its existence, other doctors served on the faculty. Drs. A. B. Stuart, F. Lessing, S. B. Sheardown, and A. Young taught at different times. The original board of instructors, however, was the backbone of the organization and they continued their services from the beginning until the school was discontinued between 1882 and 1886.

Dr. Darwin A. Stewart, who had much to do with the school, was a typical pioneer physician, who built up a large practice, and endeared himself to a large circle of patients and friends. He settled in Winona in 1870 and remained there until his death in 1914. During this time he held many public offices and positions of honor in the community.

The physicians of Winona County numbered about one hundred in the year 1870. Many of them practiced at Winona, the population of which, estimated at eight thousand, comprised more than a third of the inhabitants of the county. Several small towns had no physician and called upon those of Winona in times of need. Elba, with a population of 700, Minnesota City, Dresbach, and New Hartford had no physicians during the early seventies. Occasionally Winona physicians were called outside the county or across the river.

During the seventies the birth rate, as indicated by figures for the county and

for the city of Winona, greatly exceeded the death rate. For example, the births for the year 1874 in Winona City numbered 226, while only 130 deaths were recorded. For the county, figures of 1872 show 674 births and 322 deaths. These statistics and the number of incoming settlers are evidence of a community still in its period of rapid growth. New physicians came with the settlers, sometimes five or six in a year.

Several slight epidemics occurred at this time. Early in 1872 whooping cough was prevalent among the children of Winona and vaccination was highly recommended for its prevention. At the same time news came of a smallpox epidemic in the East and of its spreading westward. One physician in Winona City vaccinated 150 persons in a day. This and many other precautions were advised. At the end of the year, only seven deaths from smallpox were reported in Winona, a few at Minnesota City, and none throughout the rest of the county.

Scarlet fever came occasionally in the early seventies, but become more serious in 1876, when twenty-three deaths occurred within a short time in Winona. The disease raged throughout the state during the following year.

Isolated cases of diphtheria were treated from time to time and the disease was reported to be alarming at Saint Charles in November, 1877. There were fourteen fatal cases in Winona the next year, concerning which Dr. Staples wrote in his report to the State Board of Health, "The City of Winona has a population of a little over 12,000 . . . the City has never known an epidemic of diphtheria." Although he mentioned the number of deaths occurring from the disease, such a small percentage was not to be reckoned an epidemic. However, it was considered epidemic elsewhere near Winona. Minneiska and Trempealeau were badly stricken in 1877. In the winter and spring of 1878, thirty cases occurred at Lewiston, a village of three hundred persons. Eleven of these cases proved fatal. In this instance sanitary conditions were known to be poor. Dr. Franklin Staples made a thorough investigation of conditions, continuing it for several years when the epidemic persisted during the eighties. His reports may be found in the records of the State Board of Health, of which he was then a member.

He stated that diphtheria was alarmingly on the increase and that in 1879 more than 13 per cent of deaths in Minnesota occurred from this single cause. Secondly, he emphasized the point that the disease to a great extent was preventable by sanitary means. In November, 1879, a circular inquiry concerning the prevalence of diphtheria in the state from November 1, 1878, to November 1, 1879, was issued to correspondents. One hundred and twenty-nine replies were received. Winona County numbered two deaths from diphtheria among a total of 295 (about $\frac{3}{4}$ per cent as compared to the 13 per cent stated above). Obviously the epidemic did not make much headway at Winona.

The *Scientific American* and other prominent journals quoted liberally from this treatise by Dr. Staples. Staples deserves far more mention than has been accorded him here. He was appointed by the State Board of Health to investigate the effect of the climate of Minnesota on catarrh, pneumonia, and phthisis pulmonalis. He had made studies along this line for some time and the report was published in 1875. During the same year, Dr. Staples made a report before the American Medical Association on "The Influence of Minnesota Climate on Pulmonary Diseases." He was president of the Minnesota State Medical Society in 1871 and always took a very active part in the organization. He was also Vice President of the American Medical Association and without doubt one of the most able physicians of his time in Minnesota.

No record can be found of an adequately equipped hospital in Winona during

the seventies or before. It was not until 1894 that the Winona General Hospital was organized under the guidance of Dr. Donald B. Pritchard. A city hospital and pest-house existed at the city of Winona in 1884. It was in charge of Mr. F. Deertz and under the direction of the local board of health. Mr. Deertz' residence, for such was the hospital, was kept up by himself and his family, and it is recorded that only one patient was treated there in 1884. In October, 1885, the city council of Winona received a report by the city attorney relative to the title of lots proposed to be purchased for the city hospital, but no immediate action took place. Curtiss Wedge recounts in his *History of Winona County* that Saint John Hospital conducted by the Sisters of Saint Joseph was the first adequately equipped hospital in Winona. This was discontinued in 1904 but no date can be found of its foundation.

The Homeopathic Medical Society of Southern Minnesota became an active organization during the seventies. Several of the physicians practicing in Winona at this time belonged to the homeopathic school, among them Dr. T. A. Pierce. The fact that there was good natured contention between the two schools is shown in an incident which took place at the 1882 meeting of the Winona Board of Education. There were eight members of the board, and they stood evenly divided. With Drs. J. B. McGaughey and T. A. Pierce as candidates for president, one hundred and thirty-eight ballots were cast, mostly four for one doctor and four for the other doctor, with an occasional varying vote for some other member of the board. It is recorded that after a monotonous session of seven hours, the board adjourned until April 26, when the dogged determination of the friends of their respective candidates continued unabated until 2 o'clock on the following morning. On the 187th ballot, Dr. J. B. McGaughey, the "old school" physician, was elected, his victory finally being recorded as by a unanimous vote. An explanation given by one of the members was that a traitor fled to the enemy. This determined and protracted struggle was not actuated by personal or political feeling, but by the professional pride of adherents of the two candidates who belonged to different schools of medicine. During both sessions of the board when the balloting was in progress, good humor prevailed, and no bitterness of feeling was engendered thereafter.*

During this decade, several new members were taken in to the Winona County Medical Society. Dr. Darwin A. Stewart, who graduated from the College of Physicians and Surgeons of New York City in 1869, was made a member in 1871. Dr. Ferdinand Lessing came in 1875 from Wabasha, and the same year became a member of the society. For several years he held the office of county coroner. In 1876 Dr. Arnold P. Gilmore and Dr. Arthur B. Young, both new arrivals, joined the society. Gilmore was an eye, ear, and throat specialist of high reputation, who had received his training at the Jefferson Medical College. His stay in Winona was brief for he moved to Chicago in 1879. Dr. Young came from Minneapolis in July, 1875, and immediately became a partner of Dr. J. B. McGaughey. Nine years later, Dr. Young left Winona City and took up his abode in Prescott, Wisconsin.

Dr. Henry B. Wedel, who was an organizer of the medical society in 1866, became a member of the Winona County Medical Society in 1879 and was elected president for that year. He arrived in 1862, having recently graduated with distinction from the medical department of the University of Pennsylvania. His career is marked by three years of active surgical work during the war. Not long after his return, he relinquished his practice and became associated with William Netter in the drug business. Twelve years later, he

*This incident is quoted from the "History of Winona County Minnesota" by Curtiss Wedge.

again began to practice and it was about that time that he was elected to membership in the Winona County Medical Society.

Dr. Thomas McDavitt, who graduated from the Chicago Medical College in 1879, was admitted to the society in 1882, and became president the following year. Dr. J. W. Scott, who located at Saint Charles in November, 1882, was almost immediately proposed for membership in the county medical society and was admitted a short time later. He had graduated two years before from the medical department of the University of Wooster. In 1883 Dr. James B. Cole of Minneiska, son of Dr. James M. Cole, and Dr. Thomas W. Sheardown of Stockton, son of Dr. S. B. Sheardown, became members of the medical society. Neither of these young doctors was a permanent resident of Winona County. At the same time, Dr. Wm. A. Chamberlain of Saint Charles became a member. Chamberlain moved to Winona the same year with his wife and infant son.

Drs. C. A. Boyd of Lewiston, Edward D. Keyes, Edson Rhodes, Rudolph C. Teschan of Winona, and Wm. J. Newberry of Minnesota City were made members in 1885.

The obvious limitation of membership and the reputations of the older members speak well for the quality of the society. It was, therefore, a recommendation for the young men to be admitted to membership during those pioneering years.

About 1885 a local medical organization grew up at Winona. It held monthly meetings at the offices of different members, one doctor being appointed essayist for each evening. The presence of Drs. Teschan, Cole, Keyes, Staples, S. B. Sheardown, T. B. Sheardown, McDavitt, McGaughey, Rhodes, and Seilers of Alma is recorded. Judging from the available material, it was a loosely organized, conversational type of society. Several reports, essays, or case histories were read at each meeting and discussion followed. The health of the community was a matter of principal concern among them.

During the last few years with which this essay is concerned, two severe epidemics occurred in the state and surrounding territory, both of which were continuations of those of the preceding decade. The diphtheria epidemic which prevailed in the state during the 1870's continued to take a large toll. Deaths in the state resulting from this disease during the year 1881 numbered 1,397 or 12.12 per cent of the total mortality. It seems scarcely to have touched Winona County until 1885 when an outbreak occurred at Saint Charles. The Saint Charles newspaper correspondent wrote:

"For a long time nothing has created such an excitement in Saint Charles as the diphtheria controversy between the Board of Health and Dr. Burt."

The exact nature of the controversy was not recorded, but it does suggest active concern for the health of the village.

Public schools of Saint Charles were closed in October, and though they opened in November, attendance was greatly reduced. A specimen of water from the well in the school yard was sent to Saint Paul for analysis, and proved to be unusually pure and free from organic matter. However, the sanitary conditions were known to be in need of improvement. During the winter and spring of this year, seven deaths from diphtheria were reported at Winona. No comment from the local health officer has been found.

Statistics show an extremely serious series of smallpox outbreaks throughout the state in the years 1880 to 1885. In 1881 the local board of health at Winona required every person over three months old to be vaccinated, and

most of the citizens complied with the requirement. The city remained free from the disease during these years. Again in 1885 pressure was brought to bear by the health board, which recommended to the Board of Education that all children attending public schools should furnish evidence of having been successfully vaccinated. The report was tabled, however.

Two or three deaths were reported in the county each year as a result of diphtheria but the disease did not become epidemic. Scarlet fever proved to be a menace during this period, especially to children. Several severe cases were reported at Winona and at Utica in the summer of 1882. Two years later, four deaths were reported among children at Winona. In January, 1885, the disease prevailed at Saint Paul but "not to an alarming degree at Winona." In March, it was recorded that "scarlet fever prevailed in a mild form to a considerable extent at Winona."

Although measles was not reported elsewhere during this period, a severe outbreak appears to have occurred at Dakota village. The following quotation is from "The History of Winona County, Minnesota" published in 1883:

"In May and June, 1882, the village of Dakota was visited by the most severe and alarming sickness that ever struck this healthy little town. Charley Dalton, while on a trip west of St. Paul, caught what was supposed to be the measles. After returning home, he came down very sick. In a few days the whole town became helplessly prostrated. Physicians were called and pronounced it the measles and a slight form of scarlatina. For four weeks every family in town was so stricken that there were not enough well to wait on the sick. . . . The sickness spread to surrounding vicinities, and was very severe in some families. . . ."

Other ills which touched the county at this time included malarial fevers which prevailed around Minnesota City quite extensively in October, 1881, and were thought to be caused by the extreme wet and heat of the summer.

In January, 1883, a neuralgic epidemic, called epizootic, prevailed in Winona and in adjacent Wisconsin towns. The disorder was characterized by severe earache, acute pains in the head, teeth, and face, discharges from the ears and nose, and more or less fever.

Much sickness was reported at Dresbach in the fall of 1883, the details of which remain unrecorded. In the winter of 1884 and 1885, whooping cough was common at Minnesota City. The following August, Saint Charles reported the prevalence of influenza.

The deaths of the county in these five years resulted mainly from non-infectious or non-contagious diseases. Most of the deaths of 1881 resulted from heart disease. A typical report by the Winona City health officer in August, 1883, recorded twenty-two deaths. Six were caused by dysentery, five by diarrhea, one by cholera infantum, two by meningitis; none resulted from contagious diseases. In 1884, also, no epidemic touched the city; the mortality rate was .015 per cent; the population being 16,000 and the number of deaths 237 for the year. It was noted that "a large number of the deaths of young children and most cases of puerperal fever would not have occurred under proper hygienic management."

Local boards of health increased in number in the state about 1885 and became better organized. A conference of state and local boards of health and popular sanitary councils for southeastern Minnesota met in October, 1885. Among those present were Dr. J. W. Scott of Saint Charles, and J. P. Mumford, who was sanitary inspector of Winona though he did not hold a medical degree. Dr. Franklin Staples continued to hold office as health officer of Winona.

These local boards of health were not always composed of physicians, but usually included some outstanding members of the community who would have an interest in the sanitation and well-being of the village.

It is interesting to note that in the year 1885 Winona and other river towns presented a protest through the State Board of Health to the governor to the effect that the time had come for putting an end to defiling the Mississippi River by making it the cesspool of the state. This, however, was ineffective. From that time until now, the State Board of Health has continued its efforts in that direction, and only recently has its protest received proper consideration.

Physicians who came to Winona County in 1886 were Thomas A. Pierce and C. N. Clark. In 1887 F. O. Drake came to Winona from Red Wing and D. C. Lewis from Brooklyn, N. Y., to Saint Charles. H. S. Wahl moved from Minnesota City to Winona; A. H. Trow came from Chatfield to Dakota; and J. Martin left Saint Charles to locate in Little Falls. In July, 1887, there were twenty-two physicians in Winona County.

In November, 1888, a bazaar held for the benefit of Saint Johns Hospital netted almost three thousand dollars, and helped greatly to maintain that institution. In 1890 a considerable sum was raised for the same purpose by a series of ball games among the physicians, dentists, and pharmacists of Winona. The doctors lost all their games. Dr. Sheardown died in 1888. Dr. Donald R. Prichard came to Winona in the same year. During the year 1891 J. W. Timmons came to Winona from Homer, and Royes and J. Wilson to Pickwick. E. D. Stoddard moved to Stewartville, Clark Christian to Witoka, T. R. Wilson to Pickwick, and John Morrison to Winona, from New York, and Dr. English arrived. In 1893 S. C. Vandergee came to Wyattville. Francis F. James to Winona from Tracy in 1894; in the following year W. E. and Louise Aubin became residents of the town. In 1896 Dr. Slocumb and Dr. Steinbach located there. Other physicians who selected Winona as their home were E. S. Muir, N. S. Lane, Oswald Leicht, Francis Roberge, and Engleken, who came in 1898; and J. F. Millspaugh and O. F. Gile in 1899. Dr. Gile later moved to Dakota. Dr. P. B. Blair arrived in 1900. In the same year Dr. Forger was located at Elba, Dr. Wilmot at Clyde, Dr. Hutchins at Whitehall, and Harvey Brown at Rollingstone.

We have been unable to trace the further history of many of these men. Dr. Louise Aubin, however, moved to Stillwater, while Drs. E. D. Keyes, John Dwight Keyes, H. M. Lichtenstein, Donald B. Prichard, and Charles P. Robbins remained in Winona, Dr. Hiram C. Baer at Saint Charles, and Dr. O. F. Gile at Dakota.

The presidents of the Winona County Medical Society from 1885 to 1900 were as follows:

1885 —Franklin Staples	1891-3—Franklin Staples	1897 —D. B. Prichard
1886 —J. M. Cole	1894 —J. W. Scott	1898 —H. M. Lichtenstein
1887-8—R. C. Teschan	1895 —J. M. Cole	1899 —E. D. Keyes
1889 —S. B. Sheardown	1896 —W. A. Chamberlain	1900 —J. W. Scott
1890 —E. D. Keyes		

J. B. McGaughey was secretary of the society from 1873 to 1908.

A medical organization known as the Winona Medical and Surgical Society met for a time in the early part of 1890. It is stated that the society had existed in name only for a period of two years, and that it was reorganized at this time. Meetings were to be held fortnightly. At the meeting held on February 7, 1890, Dr. McGaughey was elected president, and Dr. McDavitt was chosen secretary. The last meeting of which record has been found was held on February 20, 1890.

(To be continued in the June issue)

President's Letter

THE Committee on Tuberculosis has an ambitious program. It hopes to eradicate tuberculosis from our state—not in general, but completely. The members of the committee believe this can be done.

Three decades ago tuberculosis occupied first place as the cause of death in the United States; today it is seventh. In 1918 there were 2,543 deaths from tuberculosis in our state; in 1938, there were 816, and last year 804, a rate of thirty per hundred thousand.

The factor which encourages the committee to this bold hope is the specificity of the tuberculin test. Bovine tuberculosis was very prevalent up to 1917. In that year testing of cattle by the tuberculin test and the removal of all positive reactors was started. This resulted in a prompt lessening of the incidence of the disease. Post mortems of positive reactors showed tuberculosis in 97 per cent. Today all but six counties in the nation have been accredited. These six counties are in California, which state has been slow to use the test. In England, where the test is not used, bovine tuberculosis is just as prevalent as it was in 1915; and among human beings, 25 per cent of the cases of tuberculous meningitis, 50 per cent of the cases of lupus, 20 per cent of the cases of tuberculosis of the bones and joints, and even 3 per cent of the cases of pulmonary tuberculosis are of the bovine type.

The plans of the Committee are not fully formulated but in general will consist of the following:

1. Apply the tuberculin test to the entire personnel of each household in every county.
2. Make a radiographic study of every positive reactor.
3. Make additional laboratory and medical examination to complete the diagnosis.
4. Provide adequate segregation and treatment for each patient as long as he is infectious.

A more economical plan would be as follows:

1. Concentrate x-ray studies particularly on the tuberculin sensitive adults present in each home in which tuberculin sensitive children are found.
2. Radiograph adults who are positive reactors and whose children have negative reactions to tuberculosis.
3. Reapply a tuberculin test to all future members of population and all who were negative on previous survey at least annually.
4. Concentrate x-ray studies particularly on tuberculin sensitive adults in each home in which tuberculin sensitive children are found, and repeat them at least annually.

To be effective, it will require the coöperation of every physician in the state. A state-wide program of education must be carried out efficiently. It will be necessary to raise funds for filming, hospitalization of active cases, and for follow-up work.

This is a large program which must be continued for many years. Such diseases as diphtheria, smallpox, typhoid, yellow fever have been brought under control by medical science. Considering the long course of the disease, its universal and continuous incidence, and the economic and social loss caused, tuberculosis has been a far more serious disease. If the White Plague can be eradicated, it will be the greatest feat ever accomplished by medical science.

BERTRAM S. ADAMS, President

Minnesota State Medical Association.

STATE MEETING—1940

THE annual State Medical Association meet-
ing at Rochester last month fully satisfied
expectations, both as to attendance and scientific
program. This meeting has come to be one of
the largest annual meetings in this part of the
country. Some 3,400 registrations included
about 2,000 physicians from Minnesota and sur-
rounding states.

The new Rochester auditorium, which was
used for the first time for a medical meeting,
proved ideal, for the acoustics of the amphi-
theater obviated any need for a loud speaker and
the adjoining rooms well accommodated the
scientific and commercial exhibits.

Officers chosen by the House of Delegates
included Dr. B. J. Branton, Willmar, president;

Dr. Albert Fritsche, New Ulm, vice president;
Dr. Frank J. Heck, Rochester, second vice presi-
dent; Dr. Benjamin B. Souster, Saint Paul, Sec-
retary (re-elected); Dr. W. H. Condit, Minne-
apolis, treasurer (re-elected). Dr. W. W. Will,
Bertha, and Dr. E. A. Meyerding, Saint Paul,
were re-elected speaker and vice speaker, respec-
tively, of the House of Delegates. Dr. W. A.
Coventry, Duluth, and Dr. W. F. Braasch,
Rochester, were re-elected A.M.A. delegates,
with Dr. J. C. Hultkrans, Minneapolis, and Dr.
W. L. Burnap, Fergus Falls, re-elected alter-
nates. Dr. Carl M. Johnson, Dawson, was elected
councilor of the Third District to replace Dr.
B. J. Branton.

Dr. Henry Ulrich, Minneapolis, was elected
by the Editing and Publishing Committee of
MINNESOTA MEDICINE as Associate Editor of
the journal to take the place left vacant by Dr.
Gilbert Cottam.

The full capacity of the dining room at the
Rochester State Hospital was taxed by some 465
members, wives and guests at the banquet Tues-
day evening. Unfortunately many were unable
to obtain tickets. Following the banquet the
diners were addressed by Governor Stassen who
spoke in his characteristically forceful manner
on fundamentals and trends in government and
announced his intention of appointing in the near
future a commission to draw up a suitable
memorial to those two outstanding Minnesota
surgeons, Drs. William J. and Charles H. Mayo.
The address of Mr. Bernard H. Ridder, pub-
lisher of the *Saint Paul Pioneer Press and Dis-
patch*, on Hitler proved particularly interesting
because of his personal acquaintances with the
Führer.

The prize presented each year by the Southern
Minnesota Medical Association for the best
scientific exhibit at the State meeting was this
year awarded to Dr. Carl W. Waldron, Minne-
apolis, for his exhibit of Fractures of the Facial
Bones. Honorable mention was given Harry
Wilmer of the Department of Pathology at the
University of Minnesota Medical School for his
exhibit of Injected Kidneys.

Saint Paul was chosen as the place of meeting
for 1941.

SCUTTling THE EPONYMS

EVER since medicine in all its branches really began to advance it has become increasingly evident that something would have to be done about the various nomenclatures. These had simply accumulated, from the earliest times, without any semblance of order or system. Anatomic structures, pathologic conditions, clinical symptoms, methods of diagnosis, diseases, surgical instruments, surgical operation, et cetera, were often given the names of those who had discovered or first described them, without any other indication of their nature or function. It was a pretty custom and wholly unobjectionable in the days of vague medical knowledge, when sentiment and a desire to pay tribute to great names had been in the ascendent over a long period of time, but it was totally out of step with the trends of modern times, in which not only are precise facts the basis of all scientific progress but accurate terminology predicated on orderly planning are equally essential.

Strangely enough the first serious effort to correct this situation came in the field of anatomy. The Anatomische Gesellschaft, the leading society of anatomists in Germany, held numerous conferences about fifty years ago and at its ninth formal meeting in Basel, Switzerland, on April 19, 1895, adopted what is known as the BNA (Basel Nomina Anatomica) in which all eponyms had been dropped and all structures given Latin names which either described their appearance or connote their functions. It is, today, the foundation of all modern works on anatomy, although modifications, without disturbance of the basic principles, are still in course of discussion. Thus there is the NK (Nomenklatur Kommission), the British Nomenclature, in Latin and English and, finally, the International Commission to assemble and correlate all available data, the latter still in existence.

In bacteriology many difficulties arose. Some years ago a committee of the Society of American Bacteriologists spent several years in formulating a scheme of classification and nomenclature of bacterial types, which has been fairly generally accepted, in this country at least, as best meeting the varied and difficult requirements of the situation. The classification extends from

order to family and subfamily, tribe and genus, before the individual microorganism is reached. The eponymic motif has been preserved in part and turns up now and again even as high up in the family tree as in the tribe (e.g. Neisserieæ) and quite often in the genera (Gaffkye, Salmonella, Pfeifferella, Pasteurella, et cetera) and finally in the individual, as in *Clostridium welchii*, although in this instance the more familiar *B. welchii* is still in common use.

The designation of surgical operations by the names of their originators, or modifiers, has long been a source of confusion and error. To obviate this and many other weaknesses the Western Surgical Association appointed a Committee on Names of Surgical Operations more than ten years ago, composed of E. Starr Judd, Kellogg Speed, Harry P. Ritchie and Carl E. Black. Like similar efforts in other fields it proved to be an enormous task, lightened only in some degree by material help from the American Medical Association and by the tireless coöperation of several national surgical organizations and many individuals in this country and abroad. The final result was published in 1935 in a book of 100 pages entitled Names of Surgical Operations, a model of simplicity and clarity and without the use of a single eponym.

Lastly, but by no means the least, come two monumental works which are the products of enormous and effective labor and scientific judgment. These are the Standard Classified Nomenclature of Disease, published in 1935 and subject to revision every five years and the Manual of the International List of Causes of Death, revised every ten years, now in its fifth revision. It is sincerely to be hoped that these two nomenclatures will ultimately come into universal use wherever scientific medicine is practiced.

The eponyms have gone for good. No longer may we speak of Bright's disease, Scarpa's triangle or the Billroth I and II. Sentimentally we are poorer but scientifically far richer by the change, for now we have accuracy and uniformity at our behest and no one who is imbued with the real spirit of progress will have any regrets. A tremendous advance has taken place.

GILBERT COTTAM.

DR. GILBERT COTTAM

IT IS with regret that we announce the loss of the services of Dr. Gilbert Cottam as associate editor of the journal, because of his return to Sioux Falls. His numerous efforts in behalf of the journal and his contribution of numerous editorials since November, 1937, when he became an associate editor, have been greatly appreciated.

Dr. Cottam left Sioux Falls, South Dakota, some twelve years ago. After a brief sojourn in Saint Paul where he was a member of the Ramsey County Medical Society in 1931, he moved to Minneapolis where he took an active interest in the affairs of the Hennepin County Medical Society. He was editor of the Hennepin County *Bulletin* from 1935 until January of this year and gave generously of his time and literary talent to this publication.

A complimentary farewell dinner was given Dr. Cottam at the Minneapolis Club, April 16, by some sixty professional friends. Dr. George Dunn presided and brief speeches were made by two teams of guests headed by Dr. A. E. Benjamin and Dr. W. A. Hanson, the team headed by Dr. Benjamin being instructed to make only complimentary remarks about the guest of honor and the second team just the opposite. Needless to say the first team was awarded the victory by the committee headed by Dr. Olga Hanson.

During Dr. Cottam's comparatively brief residence in Minneapolis he was very active professionally and made a great many friends, whose best wishes he carries with him to Sioux Falls.

HEALTH FOR LABOR

The American Labor Party is trying to win workers over to its health program by means of a bulletin issued periodically under the auspices of its Committee of Medical and Allied Professions. The Party appears determined to present the medical issues of the day fairly and to demand a square deal for the healing professions under whatever program is ultimately adopted. Unfortunately, its medical policies, as set forth in "Health Security Bulletin," appear to have been shaped by the more radical elements of which it is seeking to purge itself. Insistence on compulsory health insurance at this time, when medical and lay opinion are united on the merits of voluntary non-profit medical expense indemnity insurance, is likely to sabotage the development of a harmonious progressive health program. Needless to say, this would cause satisfaction among Communists in and out of the A.L.P.

Except for the issue of compulsory insurance, there is no vital disagreement between the health programs of organized medicine and of the American Labor Party. Both favor state medical aid for the indigent and medically indigent. Both want the maintenance of the traditional doctor-patient relationship and professional participation in the administration of health plans.

The advocates of compulsory sickness insurance, in the American Labor Party as elsewhere, try to confuse the issue by arguing that voluntary insurance would not provide for all who need medical aid. This is true—but neither would compulsory insurance. The insurance principle—whether on a voluntary or compulsory basis—is applicable only to those employed at salaries large enough to permit the payment of premiums without serious deprivation. The unemployed and workers earning mere subsistence wages must receive state help. It is folly, in the name of health, to deprive small wage-earners of health essentials by levying a weekly tax on their already inadequate earnings. The unemployed do not come within the purview of compulsory insurance any more than voluntary.

The "Health Security Bulletin" of the American Labor Party argues that since voluntary insurance almost always leads to compulsory, we might just as well start with the latter. On the contrary, this seems to us another reason for not insisting on compulsory insurance until voluntary schemes have had their chance. If voluntary insurance works out, without the creation of a vast parasitical political bureaucracy, it will be to the advantage of the working class which, in the long run, pays the costs of government. If it fails, the profession will have less reason to oppose compulsory schemes and many valuable administrative lessons will have been learned.

The American Labor Party must realize that the welfare of the working classes is indispensable to the medical profession; the vast majority of physicians have their practice among the poor and middle class. Since medicine and the American Labor Party are united on many of their health aims, would it not be a constructive step for the A.L.P. to postpone its campaign for compulsory insurance, pending the results of voluntary medical expense indemnity, and coöperate with the profession for the enactment of measures on which they are agreed? —Editorial, *New York State Journal of Medicine*, Feb. 1, 1940.

DIAGNOSIS OF TUBERCULOSIS

The modern concept of diagnosis of pulmonary tuberculosis implies a decision as to whether or not the patient has a pulmonary tuberculous lesion; whether the lesion is healed, inactive, or active and an attempt to determine to what phase the lesion belongs, whether primary or in the stage of dissemination. Even the total absence of physical signs does not exclude the presence of a tuberculous lesion, healed or active. Advanced disease may be diagnosed by physical examinations but they cannot be relied upon for the diagnosis of progressive early disease.—P. O. KAYNE, M.D., *Pulmonary Tuberculosis*, Oxford Med. Publication, 1939.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the

Minnesota State Medical Association

W. F. Braasch, M.D., Chairman

IS GROUP PRACTICE THE SOLUTION?

Critics of the present methods of medical practice confine most of their efforts to publicizing and magnifying its deficiencies. It is being done by a continuous barrage from social reformers, medical radicals, sensational journalists and New Dealers. As a result, a section of the public is being led to discredit the medical profession and its methods of practice and to believe that there is urgent need of reform. No one is more aware of the deficiencies in the present methods of distributing medical care than the doctor himself. The trouble has been to discover the best means of overcoming the faults without serious injury to the best system of medical care that has as yet been devised. The physician, through organized medicine, has hesitated to make any radical changes for fear of unbalancing the whole structure of medical practice. He has preferred to carefully try out various plans for improvement based on practical experience. Not so the social reformer and uplifter. He does not hesitate to advocate any of a score of plans which are either based on little or no experience or which have governmental support.

"The Mountain Labored"

The main objection to the present methods of medical practice, from the public viewpoint, is, of course, its cost. Medicine cannot be made cheap without having cheap medicine. In case of a medical catastrophe the cost to a family which cannot take care of it becomes a calamity. It is for the solution of such problems that organized medicine is trying out a system of voluntary insurance at a rate which can be met by any non-indigent individual. This plan retains the advantage of a choice of physicians and personal relationship, as well as the stimulus for individual initiative.

Regrettable to say, some of the magazine ar-

ticles antagonistic to organized medicine are written by physicians themselves. In one such article not alone are the conscientious efforts on the part of organized medicine to solve their problems belittled, but, after smearing the medical profession in general, the author questions the ability of his colleagues to care for the sick as individuals. After all this, what was the solution that he offered? The mountain labored and produced a mouse-like solution: namely, Group Medicine.

Group Medicine Advocated

Group Medicine as a solution of the problems affecting medical practice was first recommended by the Majority Report of the Committee on the Cost of Medical Care, and since then has been advocated by many others. It is asserted in the recent article referred to that it would overcome many of the present difficulties involving medical practice, including the evils resulting from professional competition and such problems as the predicament of the recent graduate without sufficient practice to keep him busy. The formation of group clinics to take care of all medical practice is suggested. Even if it were possible, what a wierd form of medical practice we should have if such clinical groups thickly dotted the land. It is certainly open to question whether group practice can be adapted to meet many of the situations met with in the actual practice of medicine. While it may offer certain advantages in urban centers, it would not function so well in rural districts.

No statement is made as to how these groups are to be formed, financed, and given the various facilities which are necessary to success. It is not stated whether they are to be aided by or under government control. The impression is given that successful clinical groups can be formed out of thin air. It is apparently forgotten that

numerous attempts have been made to form clinical groups in the past and that only a very few have survived. It is generally admitted that the successful formation of a group depends upon several factors, including a strong executive at the head, a nucleus of wide clinical opportunities, and exceptional professional ability on the part of the promoters. Many a group has been formed with adequate possibilities, only to be wrecked by professional jealousy, the very objective which group practice is supposed to overcome. It could readily be imagined what would happen to any group which would be formed under durance of governmental control.

Professional Coöperation Valuable

The value of professional coöperation is fully realized by groups of independent physicians situated in urban centers, where many loose associations of this type have been formed. A working arrangement is effected whereby the patient can be examined as indicated by various specialists situated in the same office building. Financial arrangements are made so that the cost can be met according to the income of the patient. This system has had widespread adoption and has worked out very well, in a measure taking the place of a clinic. Clinical groups, however, are in existence which do not function as ideally as pictured and which have no other purpose than commercial gain. It is true that the monthly charge of some of these clinics is comparatively low and on the surface it seems surprising how much can be offered for the money spent. Closer inspection, however, will show that the standards of diagnosis and treatment offered cannot be regarded as "good" medicine. The profits in clinics of this type are often made by extra charges and by the commercial adjuncts of the clinic.

No clinical group can practice good scientific medicine by materially lowering the cost to the patient. It has been asserted that the American Medical Association is opposed to group medicine. This is quite contrary to the truth. The American Medical Association is opposed only to that type of clinical group that does not practice good ethical medicine.

Other Methods Available

It is true that the ability of the men involved is increased by closer association and by in-

creased clinical opportunities. Nevertheless, there are other methods than group medicine to accomplish this purpose among the rank and file of medical men. It is remarkable that after years of thought and investigation by social reformers and the expenditure of a large amount of money by Foundations and even by federal sources for the purpose of reform, no better solution can be advocated to solve the problems of medical practice than Group Medicine.—W.F.B.

PHYSICIANS TAKE THE PLATFORM

It is clear from the multitude of requests for speaking material that doctors are at last alive to the necessity for telling the people how the profession of medicine feels about encroachment of government into the American system of care for the sick.

Response to a recent country-wide questionnaire showed that 98 per cent of the medical men of the country were opposed to socialized medicine. The results received widespread publicity and the people who read about it are certainly justified in wanting to know why.

They have been told repeatedly that the physicians of the country back the American Medical Association in its opposition to the Wagner Health bill and compulsory sickness insurance. Many earnest men and women honestly see in these measures a welcome method for preventing sickness and saving lives. If the doctors see something else besides in such measures, just what is it the doctors see?

It is too much to expect that the general public will accept the unsupported word of the doctor in matters like these. Outside the consulting room the physician must be as explicit in defense of his opinions on public matters as the politician—and far more persuasive.

An Excellent Sign

It is, therefore, an excellent sign that doctors are accepting so many invitations to talk about the national health program and its corrolaries.

Quoted below for their assistance are excerpts from recent talks by Dr. W. A. O'Brien, Minnesota State Medical Association radio speaker and director of post-graduate medical education at the University of Minnesota, who is one of the most skillful and effective speakers in the entire country.

No Depression in Medicine

Said Dr. O'Brien:

"There has been no depression in medical progress since 1920. No period in history has seen so much progress in the prevention and cure of illness.

"Just think, for a minute, of what this phenomenal progress has meant. Before 1920, we had no insulin and diabetics—even diabetic children, were doomed to slow starvation or death in coma.

"We had no liver extract for pernicious anemia. We didn't know how to use iron for the anemia that used to be so common among young girls.

"We had no idea how to control hook worm disease.

"We knew nothing about the vitamins that have so changed our concepts of diet, nothing about nicotinic acid which performs miracles for victims of pellagra nor for the other synthesized fractions of Vitamin B which are offering new hope for so many otherwise hopeless ailments.

"We knew nothing about sulfanilamide or sulfapyridine or any of the related chemical compounds that have revolutionized our treatment of streptococcal infections, of gonorrhea, of pneumonia. Before we had sulfanilamide, for instance, we never had one single treatment that was of any real value for the blood poisoning of women following childbirth.

"Before 1920—"

"Before 1920, we had none of the new anesthetics that have made surgery safe for so many people who were deprived of it in the old days. We knew nothing about modern preparations for operation and nothing about the use of blood transfusions to combat the hazards of surgical treatment. Nothing about the measures that now make it possible, if necessary, to prolong delicate life-saving operations to nine and ten hours without harm to the general condition of the patient.

"We knew nothing about modern care for premature babies by which death rates for babies born too soon was cut in one of our Minnesota hospitals from 65 to 10 per cent in the last four years.

"What does all this mean to us?

Longer Life for All of Us

"It means longer and better life for everybody, of course. But it also means that there are more old people in the population in comparison to the young. It means, among other things, that arthritis is the most common of all diseases today, that allergies are increasing rapidly, that circulatory diseases and heart disease and cancer are taking the place in numerical importance of the old scourges of youth.

"It means, in spite of all that has been done in medicine in the last 20 years, that there is now a great unrest about medicine itself. Why? Because the aging section of the population is fearful and uneasy. It demands its ham and eggs and its thirty dollars every Thursday. It yearns, also, for free medicine—and the propagandist is quick to seize on that yearning.

"Security is the watch-word these days. But here is a curious and ironic fact; when we try to hand people security we defeat our own purpose. The truth is that we cannot give people real security. The only things that benefit any of us in the long run are the things that we get for ourselves.

Jittery Souls

"Did you ever notice the people who live on pensions or who hope to live on pensions? They are the most jittery souls on earth. They worry for fear they will not live long enough to enjoy their pensions and then they worry for fear the pensions will be taken away.

"We doctors know that, and we believe that in some things, such as illness, the people must be responsible for themselves. And, above all, that government cannot step in successfully and take that responsibility for us.

The Worse for All

"We believe that people should never be forced to go to doctors if they don't want to nor should they even be vaccinated and immunized against their will. If government does step in, assume that responsibility and enforce those measures, we believe it will be the worse for the patient and the worse also for medical progress.

"Of course, there are some special fields such as tuberculosis and mental disease in which we have welcomed government assistance. We know that government also serves an essential function in the control of public health.

A Different Story

"The story is entirely different, however, for the ordinary illness of the ordinary person. For these illnesses and for their own health, the responsibility belongs to the people themselves. And if the insurance principle should prove to be practical for payment of medical costs, then in these plans too the people should help themselves. We are already showing that it can be done in our hospital service associations and in our college health services. Certainly there is no reason why we should abandon the principle of self help simply because as a nation we are older than we used to be and are therefore subject to the fears and distresses of age.

Unselfishness for Age

"Perhaps the most important thing for any of us to learn is how to grow old gracefully. Courage and optimism and unselfishness are attributes of youth but they can be cultivated in age, as well.

"We must cultivate them in America if we are to avoid the unhappy consequences of our fears and especially if we are to keep the way open to medical progress in the United States."

REGULATING VITAMINS

Last week, the Food and Drug Administration got around to the vitamin industry.

Tentative regulations were set up covering vitamins from A to K and, if they go through, they are expected by *Business Week* to pare down the biggest slice of the fat vitamin pie—that is, the sales from the long-established and eminently marketable vitamin D, the “sunshine vitamin.” Hearings were scheduled for April 29.

The portion which is going to cause the major part of the shouting comes in one sentence requiring flatly that the labels of all foods making Vitamin D claims carry the statement: “When the skin is adequately exposed to direct sunshine, there is no established need for Vitamin D in the diet.”

Other telling points in the new regulations are:

1. All dietary foods, regular foods fortified with vitamins or minerals and so-called pharmaceutical concentrates, both of which come under the guns of the new regulations, must state on the label the dietary properties on which their claims are based.

2. Labels must tell whether recommended daily dose or serving comes up to the minimum vitamin requirements set up by the FDA.

3. If claims are based on a vitamin or mineral not yet established as necessary to human nutrition, labels must make this clear.

American Cult

Says *Business Week*:

“Whatever the outcome of the hearing set for April 29, FDA has bitten off a very sizable hunk to chew. In the past ten years, there has grown up in America what amounts to a vitamin cult, with its worshippers ranging from the Park Avenue socialite who pays her doctor \$25.00 a visit to find out that she has a B deficiency to the Montana cowboy who orders a package of capsules from Sears Roebuck or Montgomery Ward. Today, a good sized drug store stocks around 500 separate vitamin products. . . .

“Supplying the country with its A B C’s is an industry as complex as the vitamins it sells. A complete picture would include almost every big pharmaceutical house in the country, a fat slice of the food and cosmetic industries and any number of assorted concerns which manage to tie their advertising and promotion to the vitamin fad. Behind these are the companies which supply vitamins in bulk to the drug, food and cosmetic industries.

Millions for Vitamins

“Just how big the sales of vitamin concentrates and vitamin-impregnated foods are annually is not known.

A fair estimate, however, is that drug stores marketed \$56,000,000 worth of vitamin products last year. Sales of vitamin-impregnated foods probably pass that estimate. Vitamin concentrates and vitaminized cosmetics also move across department stores and are distributed by mail. And that does not take into consideration the tremendous sales of vitaminized food for animals and plants. Practically every chick in the country gets its ration of Vitamin D and Vitamin B tablets are on the market for the well-cared for garden.

Merck’s Acid of Life

“Some idea of the rapidity with which vitamins have forged ahead and of the complexity of the business the FDA is trying to regulate may be gathered from the fact that no less than five vitamins or factors of vitamins have been discovered or synthesized within the past few weeks. At least one of these, pantothenic acid, one of the mighty B complex, popularly known as ‘acid of life,’ has first class commercial possibilities. Option on the new vitamin is held by Merck whose chemists coöperated with Dr. R. J. Williams (brother of Bell Telephone Williams) in synthesizing it.”

Perles and Vitawater

The Vitamin Beverage Corporation is a new contender whose advertising for vitaminized Ginger Ale and Vitawater is just breaking in the national magazines. Incidentally, the head of this new corporation is also behind the U. S. Vitamin Corporations which sell Vi-Syneral to doctors and also the Dietetic Research Laboratories which sell vitamin and mineral “perles” on a “beauty-through-health” basis.

Seven Takers for “Health Insurance”

Most interesting of all, perhaps, is the brand new “health insurance” that the U. S. Vitamin Corporation is promoting in order to sell its Vi-Syneral in bulk to big corporations.

The idea is that employees are to get their vitamins in wholesale lots, employers and employees splitting the cost after the Social Security pattern. So far, says *Business Week*, James Burns, head of the corporations, claims seven-takers for the idea. And it appears also that U. S. Vitamin may expand still further if a vitamin-hormone product under their option which is now being tested in the Paris laboratory of Dr. Casimir Funk, is successful.

Still left to the FDA to consider are the vitaminized cosmetics which do not as yet come under their jurisdiction.

Actually, most of the big names in the vitamin business admit that when all of the tumult and

shouting and expense of revamping labels and formulæ are over, they will be glad the FDA stepped in.

AMA Is Only Check

The vitamin industry has not been notably successful in regulating itself and the more ethical producers have shuddered at practices which threatened to discredit good and bad alike. What small measure of control there has been has been exercised by the American Medical Association which has consistently opposed wholesale fortification of foods, drugs, and cosmetics, pointing out that the average adult gets all the vitamins he needs from a well-balanced diet and that cases of real deficiency are subjects for a doctor's care.

INTERESTING STATISTICS

(Monthly Editorial Prepared by the Medical
Advisory Committee)

A perusal of the malpractice cases brought against members of our Association during the last year and reviewed by the Medical Advisory Committee developed some interesting statistics.

Number one in the list of complaints is the fracture cases. Thirty-three per cent were brought as the alleged result of improper diagnosis and improper or poor treatment.

Your Committee recommends that the State Fracture Committee and the component county societies stress the matter of fracture treatment to the fullest during the coming year. There should be no let down in the study of this most dangerous of all fields from a medico-legal standpoint.

Number two is the complications of some forms of dermatitis. The misuse of the x-ray and other modes of applying light rays are the complaint.

Dermatological conditions are first seen by the general practitioner as a rule. If complications arise and the use of x-ray therapy is necessary, only those fully versed in its use should apply it. It is a dangerous instrument in unskilled hands.

Number three is the complications following tonsillectomies alleged to have been improperly performed causing loss of voice and so forth.

Tonsillectomy has become an every-day feat performed by the skilled and the unskilled. Ant-

icipated results are only obtained by close attention to the details of pre-tonsillectomy and post-tonsillectomy treatment, as well as a knowledge of the anatomy involved and proficiency in surgical performance.

Number four is the complications following intravenous and intradermal injections of various drugs: Neosalvarsan, "cold shots," varicose vein injections and so forth.

These have been unusually numerous this last year. This manner of treatment should not be considered lightly. Large amounts have been asked in damages in these cases.

Number five shows a miscellaneous number of other alleged wrongs committed by the medical man, for example: Negligent examination, improper talking, sponge left in wound, hernia following appendectomy.

This group shows the pitfalls of the general practice of medicine. Every case is a potential suit. Proper care of the patient by meticulous attention to details will avoid most of these. Again, we bring to the membership's attention, the curse of the unbridled tongue when discussing another man's work.

—B.J.B.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. Dubois, M.D., Secretary

Quack Doctor Pays \$500.00 Fine in Minneapolis

Re: State of Minnesota vs. William E. McCoy
(2 cases).

On April 1, 1940, William E. McCoy, 35 years of age, and who holds no license to practice any form of healing in the State of Minnesota, pleaded guilty in the District Court of Hennepin County, to an information charging him with the crime of practicing healing without a basic science certificate. McCoy was fined \$500.00 by Judge W. W. Bardwell and which fine was immediately paid by the defendant. McCoy, on the same date, entered a plea of guilty to an information charging him with performing a criminal abortion on a 35-year-old divorced Minneapolis woman. On this charge, Judge Bardwell sentenced McCoy to a term of 4 years in the State Reformatory at St. Cloud, and the execution of this sentence was stayed for 3 years, upon condition that the defendant refrain from practicing healing in any manner in the State of Minnesota, and that he also refrain from engaging in any abortion activities. The complaint charging McCoy with practicing healing illegally, was filed by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners, and was based on McCoy's maintaining an office for the practice of healing at 316 Masonic Temple Building, Minneapolis.

McCoy told the Court that he resided at 594 Ashland Avenue, St. Paul; he stated that he had no medical training of any kind, but got into the perform-

ing of criminal abortions through the National Health Service Bureau which McCoy formerly operated at 1591 University Avenue, St. Paul. McCoy, at that time, was engaged in the sale of a medicinal preparation at \$5.00 per bottle, which was advertised as being beneficial in cases of delayed menstruation. Apparently, the preparation was a failure for McCoy stated that he was soon engaged in the performing of criminal abortions. McCoy was arrested by the St. Paul Police Department in February, 1939, in connection with his operation of the National Health Service Bureau and finally was permitted to plead guilty to a violation of the State Pharmacy Law, for which he was fined \$50.00. In the present cases, McCoy was arrested in his office by members of the Minneapolis Police Department, on March 14, 1940, at which time his complete stock of surgical instruments and various medicinal preparations were confiscated. The Minnesota State Board of Medical Examiners approves of the manner in which the present cases were disposed of by the Court. Judge Bardwell made it very plain to the defendant that the Court was not imposing any fines in his case in the future, but that any unlawful activities on the defendant's part would result in a trip to the St. Cloud Reformatory. McCoy stated to the Court that he was absolutely finished with any such activities, and he will have no one to blame but himself if he is obliged to serve a prison term at St. Cloud. The Medical Board also wishes to acknowledge the splendid work done in these cases, and the coöperation given by the Minneapolis Police Department, and particularly by Lieutenant Blanche Jones and Mrs. Carrie Bystrom of the Women's Bureau.

Supreme Court Affirms Conviction of Minneapolis Physician

Re: State of Minnesota vs. George Frederick Lemke.

On January 26, 1940, the Supreme Court of Minnesota affirmed the District Court of Hennepin County in denying the defendant a new trial. The defendant was a duly licensed physician and surgeon in the State of Minnesota, until his license was revoked by the Minnesota State Board of Medical Examiners on February 11, 1939, for immoral, dishonorable and unprofessional conduct. Dr. Lemke was found guilty by the Medical Board of procuring, aiding and abetting a criminal abortion on a twenty-two-year-old Saint Paul girl. The girl was found dead in Dr. Lemke's office at 512 Pence Building, Minneapolis, on December 10, 1938. On February 25, 1939, Dr. Lemke was found guilty by a jury of the District Court of Hennepin County, of manslaughter in the first degree growing out of this case. He was sentenced by the Honorable W. W. Bardwell, Judge of the District Court, to a term of not less than five, and not more than twenty years at hard labor in a state penal institution. On May 17, 1939, Judge Bardwell denied Dr. Lemke's motion for a new trial, following which Dr. Lemke appealed to the Supreme Court of Minnesota. Following the Supreme Court's affirmation of the order of the District Court Dr. Lemke filed a petition for a rehearing, which was denied by the Supreme Court on February 28, 1940. Dr. Lemke was received at the State Reformatory at St. Cloud on March 1, 1940, to begin his sentence.

Dr. Lemke was born in Saint Paul, June 29, 1879, and graduated from the College of Physicians and Surgeons in Baltimore, Maryland, in 1906. He was licensed in Minnesota on June 26, 1908, by reciprocity with the State of New Jersey. Dr. Lemke was also licensed to practice medicine in the State of New York in 1907.

WOMEN'S AUXILIARY

MRS. A. C. BAKER, Fergus Falls, *President*

MRS. E. V. GOLTZ, 2259 Summit Avenue,
Saint Paul, *Publicity Chairman*

Ramsey County

On March 25, the Ramsey County Medical Auxiliary held a regular meeting at the home of Mrs. John A. Moga, 948 Portland Avenue, Saint Paul. Miss Roselle Bezazian, pianist of the Summit School Music Department, played a program arranged by Mrs. G. Douglas Brand. Mrs. John J. Ryan, hospitality chairman, arranged the tea which followed. Mrs. Eugene Scott and Mrs. C. Harry Ghent poured.

The Auxiliary gave a Public Relations tea on Tuesday, April 2, in the Ramsey County Medical library in the Lowry Medical Arts Building. The presidents and secretaries of all women's organizations of Saint Paul were invited, in addition to the guests invited by the members of the Auxiliary. About 550 women were present.

Mrs. G. Douglas Brand arranged the program which included an address by Dr. William A. O'Brien, Associate Professor of Pathology and Public Health at the University of Minnesota, and the reading of the Broadway comedy "What a Life" by Mrs. Donald Bacon, a member of the Auxiliary. The following members assisted Mrs. Brand with arrangements: Mmes. John J. Ryan, E. V. Goltz, Lloyd Dack, Gordon R. Kamman, J. R. Aurelius, Bernard O'Reilly, and Mrs. C. Harry Ghent, president of the auxiliary.

Pouring tea were the former presidents: Mmes. Harry P. Ritchie, E. C. Eshelby, and William H. Hengstler.

* * *

A Last Reminder

Make your reservations now, for the 18th Annual Convention of the Women's Auxiliary to the American Medical Association to be held at the Hotel Pennsylvania, New York City, N. Y., June 10 to 14. New York has much to offer aside from the convention and you will not want to miss the opportunity of visiting New York this year.

* * *

CLIMATE IN TUBERCULOSIS TREATMENT

There are various conceptions as to what constitutes an ideal climate for the treatment of tuberculosis, but several authorities agree that certain climates are beneficial only to the extent that they permit patients to spend a maximum number of hours comfortably out of doors. A regimen of regulated rest and exercise, proper food and open-air life is considered to be the fundamental essential in the treatment of tuberculosis, and the part played by climate is believed to be subservient to the other more important considerations. Moriyama, I. M. and Herrington, L. P., *Amer. Rev. of Tuberc.*, March, 1939.

OF GENERAL INTEREST

Dr. Max Alberts of Saint Paul is chairman of the Minnesota State Medical Association cancer committee.

* * *

Dr. Herbert A. Carlson, formerly at Ah-Gwah-Ching, Minn., has gone to Minot, N. D., to practice.

* * *

Dr. Thomas E. Eyres of Pequot has recently moved into new office quarters where he has installed new x-ray equipment.

* * *

Dr. and Mrs. W. F. Nordman of Mora have returned from New York City, where Dr. Nordman recently completed a postgraduate course in medicine.

* * *

Dr. J. F. Karn, resident physician at Midway Hospital, has taken over the practice of the late Dr. T. J. Moynihan of Saint Paul, with offices at 2395 University Avenue.

* * *

A. TerLouw of Rochester, N. Y., addressed the University of Minnesota Hospitals general staff meeting, April 12, on the subject of medical movies, and the photographing of records.

* * *

Dr. H. T. Karsner, professor of pathology at Western Reserve University, will speak at the Mayo Clinic, May 23, on "The Relation of Certain Ovarian Tumors to Endocrine Disturbances."

* * *

Dr. Ellet de Berry, mental hygienist at the University Health Service, resigned several months ago to go to Sonora, Texas, where he is making his home on a ranch.

* * *

Dr. Owen H. Wangenstein, head of the University of Minnesota department of surgery, addressed a meeting of the Tacoma (Wash.) Surgery Society, March 23, on "Etiology of Acute Appendicitis."

* * *

Dr. Eva Jane Ostergren, who received her M.D. from the University of Minnesota in 1939, has become associated with her father Dr. E. W. Ostergren, in practice in Saint Paul.

* * *

Dr. Richard E. Scammon, long-to-be-remembered for his anatomy courses at the University of Minnesota, is now teaching two other courses in the Medical School: Measurement in Medicine and Medical Biography.

* * *

Dr. A. D. Prangen of Rochester delivered three lectures for the post-graduate course in ophthalmology at the George Washington University School of Medicine in Washington, D. C., in March. He also addressed the Washington Ophthalmological Society on "Some Salient Factors in Surgical Treatment of the Ocular Muscles."

Dr. Milan V. Novak resigned as instructor in bacteriology at the University of Minnesota Medical School, April 15, to go to Chicago as assistant professor of bacteriology at the University of Illinois College of Medicine.

* * *

Dr. R. V. Sherman, instructor in preventive medicine at the University of Minnesota, where he was also associated with health service, has gone to Red Wing to become associated in a clinic with Drs. R. H. Hedin and E. Jueres.

* * *

Dr. W. C. Alvarez of Rochester delivered the annual Clarence M. Jackson lecture, sponsored by Phi Beta Pi medical fraternity, on the University of Minnesota campus, April 26. His topic was "Functional Gastrointestinal Disturbances."

* * *

Dr. M. B. Visscher, chairman of the University of Minnesota department of physiology, will address the Northwestern Hospital staff meeting in Minneapolis, May 13, on "Physiological Aspects of the Problem of Shock."

* * *

Professor Thomas Addis of Stanford University Medical School will lecture on "The Treatment of Glomerular Nephritis," Monday, May 13, at 4:30 p. m. in the Medical Sciences Amphitheater at the University of Minnesota.

* * *

The National Tuberculosis Association has approved a grant of \$500 to the University of Minnesota for a study under the direction of Dr. Arthur T. Henrici of the Department of Bacteriology for an investigation of the acidfast actinomycetes in relation to tuberculosis.

* * *

Seven Rochester men addressed the recent meeting of the American College of Physicians in Cleveland, Ohio. They were Drs. A. W. Adson, E. V. Allen, A. R. Barnes, P. W. Brown, G. C. Morlock, G. B. Eusterman and L. E. Prickman.

* * *

Dr. A. W. Adson of Rochester addressed the Phi Rho Sigma medical fraternity's alumni banquet at the Minnesota Club in Saint Paul, April 20. The dinner commemorated the fortieth year of Theta Tau chapter, University of Minnesota.

* * *

Dr. Rene J. Dubois of the Rockefeller Institute for Medical Research has been given the John Phillips Memorial Award by the American College of Physicians. Dr. Dubois' work dealt with the effect of agents extracted from soil microorganisms upon experimental bacterial infections. The John Phillips Memorial Award is in memory of Dr. John Phillips who died in rescue work at the Cleveland Clinic disaster.

New at the University Health Service this year is Dr. John J. Boehrer, who received his M.D. from Johns Hopkins University in 1936 and was associated with Dr. F. H. K. Schaaf of Minneapolis prior to joining the Health Service staff.

* * *

Dr. R. Schwyzer, former Blackduck physician, is now located in Bulack, Switzerland. He is surgeon in a hospital there. The doctor has a son who is now taking military training, as is required of all young men in that country.

* * *

Dr. Bernard A. Watson, physician in the Health Service and assistant professor of preventive medicine at the University of Minnesota Medical School, resigned May 1 to go to Battle Creek, Michigan, to be associated with the Battle Creek Sanatorium as head of the division of metabolism and endocrinology.

* * *

A series of five lectures, arranged by the University of Minnesota department of physiology, were presented in April by Professor Herbert M. Freundlich, university professor of chemistry. The lectures were concerned with phases of colloid chemistry of importance to biology and medicine.

* * *

A George Chase Christian Scholarship has been awarded for 1940-41 to Dr. John E. Skoglund, clinical instructor in the division of nervous and mental diseases at the University of Minnesota Medical School, for study in clinical neurology at the Harvard University Medical School.

* * *

Dr. Albert V. Stoesser, associate professor in the pediatrics department at the University of Minnesota, and Miss Marie Druckrey of Green Bay, Wis., were married April 27 in Shawano, Wis. After a wedding trip to Virginia and North Carolina, Dr. and Mrs. Stoesser will make their home in Minneapolis.

* * *

Five members of the University of Minnesota Medical School staff will go to Bozeman, Montana, to address the Montana State Medical Association, June 19 and 20. They are Drs. Cecil J. Watson, Ernest M. Hammes, N. Logan Leven, Walter A. Fansler and William A. O'Brien.

* * *

The board of directors of the American Society for the Control of Cancer includes two Minnesota men: Dr. William A. O'Brien of the University of Minnesota Hospitals, and Dr. H. E. Robertson of the Mayo Clinic, Rochester. Dr. O'Brien's term continues until 1941 and Dr. Robertson's until 1942.

* * *

The Franklyn R. Wright lectureship in urology will be given by Dr. Reed Nesbit of Ann Arbor, Tuesday, May 7, at 8:15 p. m. in the Medical Sciences Amphitheater at the University of Minnesota. His topic will be "Hypertension in Unilateral Renal Disease." The lecture is under the auspices of the Twin City Urological Society.

Dr. K. G. Wakim of the Mayo Foundation has been appointed acting professor of physiology at the Iowa State University, College of Medicine, for a six-months' period, January 1 to July 1, 1940. Dr. Wakim assumed the teaching duties of Dr. Harry M. Hines, who is doing special work at Cornell University.

* * *

Mayo Foundation Demonstration Day was observed at the Mayo Foundation House in Rochester, April 19, when apparatus, technics and various exhibits from all departments of the Mayo Foundation and the Mayo Clinic were displayed. Dr. E. J. Baldes was chairman of the committee arranging the evening program.

* * *

The Board of Directors of the John and Mary R. Markle Foundation has awarded Dr. Cecil J. Watson, Associate Professor and Director of the Division of Internal Medicine, University of Minnesota Medical School, a grant-in-aid of \$3,600, in support of Dr. Watson's studies of the significance of the excretion of various porphyrins.

* * *

Dr. J. de J. Pemberton of Rochester was elected president-elect of the American Association for the Study of Goiter at its annual meeting in Rochester, April 15-17. He will take office at next year's convention, which is tentatively scheduled to be held in Boston. Approximately 150 goiter specialists from the United States and Canada attended the sessions.

* * *

When the Minnesota Academy of Science held its eighth annual meeting on the University of Minnesota campus April 19-20, members heard Dr. A. J. Carlson, head of the department of physiology at the University of Chicago, speak on "The Physiology of Aging."

The Minnesota Neurological Society will meet May 11 in Rochester.

* * *

If you know of patients who have suffered injurious effects from the use of proprietary remedies containing desiccated thyroid, recommended or sold for obesity, or injurious results from indiscriminate use, of two grains or less of desiccated thyroid per day, please report such cases to the office of MINNESOTA MEDICINE, 2642 University Avenue, Saint Paul, Minnesota.

* * *

Dr. Henry E. Michelson of Minneapolis was among the speakers at the New Orleans Medical conference early in April, at which Dr. Rudolph Matas of Tulane University School of Medicine was honored for his fifty years of service in medicine. Approximately 1,200 physicians and surgeons from the South attended the three-day conference. Dr. Michelson gave the lectures in dermatology.

* * *

Representing the University of Minnesota at the decennial meeting of the Convention for the Revision of the Pharmacopoeia of the United States of America, May 14, in Washington, D. C., will be Dr. Raymond N. Bieter, associate professor of pharmacology, who

OF GENERAL INTEREST

will represent the School of Pharmacy; Dr. A. D. Hirschfelder, Dr. Harold Wright, and Raymond Amberg, superintendent of the University Hospital, who will represent the Medical School.

* * *

New laboratories of physiological hygiene have been opened at the University of Minnesota under the direction of Dr. Ancel Keys, the opening being marked by an "open house," March 28 and 29. The laboratories are complete with x-ray and fluoroscope for doing roentgen kymographs in connection with the heart. A motor-driven treadmill has been installed to serve as a measure for determining the amount of work done by athletes.

* * *

Expected to return about the first of June from Peiping, China, are Dr. Irvine McQuarrie, University of Minnesota professor of pediatrics, and Dr. Frank E. Burch of Saint Paul. Both have been visiting professors for the past six months at the Peiping Union Medical College, which is under the auspices of the Rockefeller Foundation.

Dr. McQuarrie will be back at the university for the first session of summer school.

* * *

Dr. C. M. Tangen of Canby has sold his practice to Dr. J. H. Raymond of Triumph, who will take possession July 1. Dr. Tangen, who started his practice in Canby in 1925, shortly after his graduation from the Medical School of the University of Minnesota, is leaving to accept a teaching fellowship at the University. He will spend three years in study to become an eye, ear, nose and throat specialist. After his work at the University he plans to take an additional year of training in New York.

* * *

Dr. B. R. Kirklin of Rochester addressed several scientific meetings while visiting in the South. On April 16, he addressed members of the Shelby County Medical society in Memphis, and the following day he addressed the meeting of the Northeast Mississippi Thirteen Counties Medical society in Tupelo, Miss. The following week he spoke at a meeting of the Louisiana State Medical Society in New Orleans, and on April 28, he addressed the Florida Radiological Society and the Florida Medical Association in Tampa, Fla.

* * *

More than \$20,000 has been subscribed to date to the Minnesota Medical Foundation, it was reported at the April meeting of the board of trustees.

According to Dr. Robert L. Wilder, secretary, membership as of April 10 included three patrons, eighty life memberships, fifty-six annual memberships, and 105 student memberships.

* * *

Dr. Erling S. Platou, president of the Foundation which was organized a few months ago, has announced plans for a more intensive program to increase the membership among alumni and friends of the University of Minnesota Medical School.

Recently transferred to the Minnesota Medical

Foundation treasury was a Medical School Endowment Fund of slightly less than \$1,000, raised through the efforts of the late Dr. Richard O. Beard for the support of medical research. Transfer of the fund was voted by the Board of Regents at the recommendation of Dr. Harold S. Diehl, Dean of Medical Sciences.

* * *

The fiftieth anniversary of Dr. C. O. Wright's entrance into the practice of medicine was observed Monday, April 1, 1940, by the Luverne Rotary club, of which the doctor is a member. Dr. Wright received his "license" to practice medicine on April 1, 1890, following his graduation from the medical school of the University of Minnesota, and immediately thereafter began practicing his profession in Montana, as a surgeon for the Northern Pacific railroad then engaged in building its line west from Missoula. Dr. Wright has practiced in Luverne for forty-one years.

A special program was prepared for the event, including a few appropriate songs and short talks by members of the club. The speakers paid tribute to the remarkably active and unselfish service rendered by Dr. Wright during his long residence in Luverne, both as a physician and a citizen who found his greatest happiness in rendering service to others and in aiding in the upbuilding of the community. The talks were naturally interspersed with the recalling of amusing incidents at the expense of the doctor, who has been a life-long devotee of hunting, fishing, golf and other sports.

* * *

Dr. Clarence P. Truog, who has been an instructor in radiology at the University Medical School, left April 1 to be associated with James M. Jackson Memorial Hospital in Miami, Fla.

* * *

Dr. Herman Jensen, formerly of Atwater and more recently in the University Medical School radiology department, has gone to Oakland, Calif., to be associated with Alameda County Hospital.

* * *

Dr. Mancel T. Mitchell, former medical fellow in obstetrics and gynecology at the University of Minnesota, is now practicing in Eau Claire, Wisconsin.

* * *

Dr. Robert Meyer, who was formerly professor and director of the pathological institute of the first women's clinic in Berlin before he fled Germany, is now an assistant professor of obstetrics and gynecology at the University of Minnesota, where he confines his activities to research in gynecological pathology.

* * *

Dr. Gerald T. Evans has been appointed associate professor of medicine in charge of laboratory service at the University of Minnesota Hospitals. He was formerly assistant professor of physiological chemistry at Yale University Medical College.

In Memoriam

Timothy J. Moynihan 1877-1940

Dr. Timothy J. Moynihan, for some thirty-three years a practicing physician in the Midway District of Saint Paul, died March 8, 1940, following a cerebral accident two days previous.

Born on a farm at River Falls, Wisconsin, May 19, 1877, he attended the local county school and later State Normal School at River Falls. He graduated from Hamline Medical College in 1906 and took his internship at Saint Joseph's Hospital in Saint Paul. In 1907, he became associated in practice with Doctors Cannon and Balcome in the Midway district of Saint Paul and later opened an office at Raymond and University Avenues.

Dr. Moynihan was on the staff of the Midway Hospital, Saint Paul, and Saint Mary's Hospital, Minneapolis. He was also a member of the Catholic Order of Foresters, The Modern Woodmen of America and the Phi Rho Sigma medical fraternity.

Dr. Moynihan was married in 1918 to Gladys Westphal, who, with a daughter Phyllis, survives him. He was preceded in death by a brother Jeremiah in 1898, and a sister Hannah Moynihan Robinson in 1931. Also surviving him are three sisters, Mrs. Carl Yocum and Mrs. Ellen Dean of Saint Paul and Mrs. John Clifford of River Falls. Two brothers, Humphrey Moynihan of Saint Paul and Dr. A. F. Moynihan of Sauk Center.

Dr. Moynihan was not ostentatious but was a true general practitioner and loved his life work. As godfather to the youth and advisor to adults he leaves a place in the hearts of his patients and friends which can never be filled.

Dr. Moynihan was a member of the Ramsey County Medical Society, the Minnesota State and American Medical Associations.

Lida Osborn 1875-1940

Dr. Lida Osborn, for nearly forty years a practitioner of medicine at Mankato, died at her home March 11, 1940, following an illness of several months.

Dr. Osborn was born in Mankato and graduated from high school there in 1894. She taught for one year at the East Mankato school and another year at the Union school, both in Mankato. She received her medical degree from the University of Minnesota in 1900 and returned to Mankato where she had since practiced. Postgraduate courses were taken later at the Children's Lying-In Hospital in Chicago after which she specialized in women's and children's diseases.

Dr. Osborn was one of the group of physicians who organized the first clinic in Mankato, but at the time of her death she was practicing alone. She was a member of the staffs of Immanuel and Saint Joseph's

Hospitals and at different times was chairman and secretary of the Immanuel medical staff. She was a member of the Blue Earth County Medical Society, the Minnesota State and American Medical Associations.

Dr. Osborn was active in the First Presbyterian Church of Mankato and at one time was superintendent of the Sunday school. She was also a member of the Mankato chapter of the National Federation of Business and Professional Women.

Dr. Osborn is survived by a sister, Eleanor, of Niswaga and a brother, Louis M. Osborn, an attorney at Virginia.

Henry Wireman Cook 1877-1940

Dr. Henry Wireman Cook, vice president and medical director of the Northwestern National Life Insurance Company of Minneapolis, died suddenly of a heart attack, April 25, 1940.

Dr. Cook was born in Baltimore, November 8, 1877. He received his A.B. degree at Johns Hopkins University in 1898 and his M.D. there in 1902. He was medical referee in New York for the Mutual Life Insurance Company of New York from 1903 to 1905.

Dr. Cook became medical director of the Northwestern National Life Insurance Company in Minneapolis in January, 1906, a position he continued to hold until his death. He was credited with being one of the first to appreciate the value of blood-pressure reading in life insurance examinations. From 1922 to 1927 and again in 1936 he was chairman of the disability committee of the American Life convention and in 1923 served as chairman of the medical section of that organization. He served last year as president of the Association of Life Insurance Medical Directors and officially represented that organization at the meeting of the International Life Insurance Medical Congress in Paris last May.

During the World War Dr. Cook obtained leave of absence from the Northwestern Life Insurance Company to serve with the American Red Cross in Washington.

Dr. Cook was a member of Nu Sigma Nu medical fraternity. He was a member of the Minnesota Academy of Medicine and of the Hennepin County Medical Society, the Minnesota State and the American Medical Associations. He was the author of numerous papers on medical and underwriting subjects and recently collaborated with his son, Henry W. Cook, Jr., in writing a book on medical impairments and other factors concerned in life insurance risks.

Dr. Cook is survived by his wife, Ellen Davenport Cook; two sons, Henry W. Cook, Jr., of Minneapolis and Charles D. Cook, student at Princeton University; two daughters, Virginia F. Cook and Mrs. H. Brewster Atwater of Wayzata; and four grandchildren.

Dr. Cook recently returned from a vacation in the South and his seeming good health only contributed to the shock his untimely death gave his many friends. A golf and bridge enthusiast, his sociability endeared him to a wide circle of friends. He exemplified a fine type of American gentleman.

REPORTS and ANNOUNCEMENTS

MEDICAL BROADCAST FOR MAY

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:00 o'clock every Saturday morning over Station WCCO, Minneapolis (810 kilocycles or 370.2 meters) and Station WLB, University of Minnesota (760 kilocycles or 395 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota. The program for the month will be as follows:

- May 4—Functional Disorders of Feet
- May 11—Common Diseases of Feet
- May 18—Care of Feet
- May 25—Diseases of Teeth

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

The twenty-fifth annual meeting of the American Association of Industrial Physicians and Surgeons, together with the first annual meeting of the American Industrial Hygiene Association, will be held at Hotel Pennsylvania, New York City, June 4, 5, 6, and 7, 1940.

This will be a four-day convention intensively devoted to the problems of industrial health in all of their various medical, technical, and hygienic phases, with particular stress on prevention and control of occupational hazards. Important programs have been prepared, and technical and scientific exhibits will be a feature of the convention. The dinner on Thursday evening, June 6, will be the occasion of the presentation of the Wm. S. Knudsen award for the year of 1939-40.

The medical profession is not only invited, but urged to attend these gatherings as they will be of unusual interest and value to all practitioners interested in industrial injuries and illnesses.

MINNESOTA ACADEMY OF OPHTHALMOLOGY

Dr. Erling W. Hansen of Minneapolis was elected president of the Minnesota Academy of Ophthalmology at a meeting in Minneapolis, April 12.

Other officers named are: Dr. William Kennedy of Saint Paul, first vice president; Dr. Theodore R. Fritsche of New Ulm, second vice president; Dr. George McGeary of Minneapolis secretary-treasurer; Dr. Henry Wagener of Rochester, chairman of the council; Dr. R. O. Leavenworth of Saint Paul and Dr. Kenneth A. Phelps of Minneapolis, members of the council.

The Academy will conduct a meeting in Rochester, May 10.

MINNESOTA SOCIETY FOR THE PREVENTION OF BLINDNESS AND CONSERVATION OF VISION

A concerted drive to eradicate preventable blindness is the aim of the recently organized Minnesota Society for the Prevention of Blindness and Conservation of Vision.

Incorporated under state charter "not for profit," the society, which has the endorsement of the Minnesota Academy of Ophthalmology, will serve as a fact-finding group and in an advisory capacity to already established organizations.

Officers are Mrs. Alfred F. Pillsbury, president; Dr. Egil Boeckmann, vice president; Louis W. Hill, Jr., treasurer; Dr. Frank E. Burch, secretary to the directors. Other directors of the society, which has offices at 503 Hamm Building, Saint Paul, are Mrs. Edwin White of Saint Paul; Rev. G. P. Sheridan of Rochester; Mrs. George W. Plant, Dr. Guy Stanton Ford, and Amos S. Deinard of Minneapolis; Edward Freeman of Virginia; J. C. Lysen of Faribault. Some forty men and women, who are outstanding in the state's medical, welfare and educational fields, are serving on its advisory committee.

Unendowed, the society is seeking small donations from Minnesota citizens for the support of its program, which is centered around the slogan, "Over one-half of all blindness is preventable." Donations may be mailed to the treasurer, Mr. Louis W. Hill, Jr., First National Bank Building, Saint Paul.

SAINT PAUL SURGICAL SOCIETY

Some 150 members and guests of the Saint Paul Surgical Society held an annual banquet, Thursday, April 11, at the Minnesota Club, Saint Paul.

The guest speaker of the occasion was Dr. R. W. McNealy, Associate Professor of Surgery, Northwestern Medical School, Chief Surgeon of the Wesley Memorial Hospital and Chief of Staff of the Cook County Hospital, Chicago. The subject of his address was "Perforation in Peptic Ulcer: a Critical Review in 700 Cases."

Representatives of the Duluth and Minneapolis Surgical Societies were guests. Dr. V. N. Peterson, president of the Saint Paul Surgical Society, presided. Dr. Logan Levin is secretary.

UNIVERSITY HOSPITAL EXECUTIVES MEET

Meeting on the University of Minnesota campus, April 12 and 13, members of the University Hospital Executives Council reelected its officers: President, Dr. Harley Haynes, director of University hospitals at the University of Michigan; secretary-treasurer, George Bugbee of Cleveland.

Twenty-six administrative officers from hospitals at

eight universities attended the two-day session. Represented were the Universities of Indiana, Minnesota, Rochester, Cleveland, Wisconsin, Chicago, Iowa and Michigan.

The program for training of residents and internes was discussed by Dr. Robin Buerki of Chicago, director of study on the American Hospital Association commission for graduate medical education. Other topics discussed during the meeting included student nurses in hospitals, personnel, and maintenance.

WASHINGTON COUNTY

At the regular monthly meeting of the Washington County Medical Society held at the Stillwater Club rooms, April 9, 1940, a number of announcements were made, and also reports from several committee chairmen. The proposed milk ordinance was brought before the meeting, discussed at length, and the Society recommended its adoption. Dr. F. M. McCarten, who was appointed to take the course presented at the University of Minnesota on the Care of the Premature and Newborn as a member from Washington County, gave a full and very good account, both at the medical staff meeting of the Lakeview Memorial Hospital on April 5 and before the regular meeting of the Washington County Medical Society on April 9.

The Society decided to show its appreciation to the physicians who had generously given of their time and knowledge by lecturing to the members during the past year, in the form of a stag dinner at the Stillwater Club on May 14. Those "golfily" inclined are invited to come to the Stillwater Golf Club at 2 o'clock in the afternoon where they will be welcomed by the following committee: Robert M. Burns, Carl L. Larsen, Frank J. Savage, Wilhelm von der Weyer and E. M. Jones, all of Saint Paul, and Royal C. Gray of Minneapolis.

WINONA AND WABASHA COUNTIES

The ninth annual joint meeting of the Winona and Wabasha County Medical Societies, and the fifteenth annual dinner tendered by the Buena Vista Sanatorium Commission to the physicians of the counties served, was held at the Sanatorium at Wabasha Monday evening, April 8. There were thirty-three in attendance, including physicians and members of the commission.

Dr. E. W. Ellis of Elgin, president of the Wabasha County Society, officiated as toastmaster.

Following the dinner, a program was presented, arranged by Dr. R. R. Hendrickson, superintendent and medical director of the sanatorium. Dr. B. S. Adams of Hibbing, president of the State Medical Association, gave an address on "Socialized Medicine," particularly in its application to plans for sickness and disability insurance.

Dr. Adams, not long ago, visited medical centers in

several European countries, where state controlled medical practice prevails, and he contrasted medical service there with that in the United States. He stated that medical and surgical equipment, hospital service, and conditions under which doctors work there were very poor as compared with the United States, and naturally, results of treatment were not nearly so good.

R. R. Rosell, executive secretary of the State Medical Association, described the plans and policies in the state regarding sickness insurance and medical relief work.

Dr. Hendrickson presented an able paper on "The Diagnosis of Tuberculosis."

After a vote of thanks to the sanatorium management, the meeting adjourned.

POSTGRADUATE COURSE IN OBSTETRICS

The Department of Obstetrics and Gynecology of the University of Chicago and the Chicago Lying-in Hospital are offering postgraduate courses of five to six weeks in obstetrics for practitioners during the next several months. The didactic part of the courses will be given for the most part by Dr. M. W. Boynton and Dr. J. H. Morton.

The first three periods will be: April 29 to June 8; June 17 to July 20; July 22 to August 24. The enrollment is small and the fee only \$15.00. Those interested may address inquiries as follows: Postgraduate Course, Department of Obstetrics and Gynecology, 5848 Drexel Avenue, Chicago, Illinois.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The Northern Minnesota Medical Association meets in Duluth on July 19 and 20, 1940.

Dr. O. W. Parker of Ely is president of the Society, and Dr. Clarence Jacobson of Chisholm, the Secretary.

The Program Committee consists of Drs. F. J. Hirschboeck and S. H. Boyer, Jr., of Duluth, R. N. Jones of St. Cloud, and O. O. Larson of Detroit Lakes, Minnesota.

STATE MEDICAL GOLF TOURNAMENT

The golf tournament held at Rochester, April 21, in connection with the State Medical Association meeting was won by Dr. C. Hunter Shelden with a low gross of 78; second low gross was obtained by Dr. J. W. Kernohan with a score of 81.

Numerous other prizes for least number of putts, lowest scores on the par 3 holes, the most 3's, 4's, 5's and 6's, et cetera, were given. The course was in excellent condition and although the day was rather cold and windy, the play was enjoyed by some thirty-five entrants. There were sixteen prizes donated by the commercial exhibitors.

PROCEEDINGS of the MINNESOTA ACADEMY OF MEDICINE

Meeting of March 13, 1940

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town & Country Club on Wednesday evening, March 13, 1940. Dinner was served at 7 o'clock and the meeting was called to order at 8:10 by the president, Dr. James Johnson.

There were thirty-one members and one guest present. Dr. Edward B. Churchill, of Boston, was a guest at this meeting.

The following men were elected as candidates on the University Membership list, Drs. Nordland and Cole acting as tellers: Dr. Harold S. Diehl, and Dr. M. B. Visscher.

The secretary read some proposed changes in the Constitution regarding the method of procedure in the election of new members. These will be published on the monthly program and voted on at a subsequent meeting.

The scientific program consisted of the following case reports:

BENIGN ADENOMA OF THE BRONCHUS

KENNETH PHELPS, M.D.

Minneapolis

Adenoma is the most frequent benign tumor occurring in the bronchial tree. This type of growth can now be recognized pathologically and is being more frequently diagnosed clinically. It is of importance because a cure is often possible.

Pathologically, these tumors are said, by some, to represent a congenital anomaly as the tumor has a marked resemblance to fetal lung. Others say they originate from the bronchial mucous glands. Some state the smaller bronchi have no such glands and therefore adenomas are found only in the larger bronchi.

Some compare them to the carcinoid tumors of the intestinal tract or to the mixed tumors of the parotid and do not classify adenoma as exclusively a benign tumor. Earlier pathologists were apt to diagnose this tumor adeno-carcinoma.

Microscopically, the epithelial covering is seen to rest on an intact basement membrane under which is a very vascular layer of loose connective tissue. This vascular layer is so characteristic that some call this tumor "vascular adenoma." The tumor consists of regular, cuboidal and cylindrical cells, arranged in solid columns or acini. They are uniform in structure and staining characteristics, contain round or oval nuclei and lack mitotic figures. Rarely does the tumor extend into the wall of the bronchus, but when this occurs complete eradication is considerably more difficult.

The lung parenchyma is never invaded and metastases do not occur.

Adenoma of the bronchus occurs more frequently (60 per cent) in women, between the ages of twenty

and forty. It grows slowly and the only symptom may be hemoptysis. In some women this occurs more frequently during the menstrual period. The characteristics of the hemoptysis are that its onset is sudden, without permonitory signs and it may cease as abruptly with no further streaking of the sputum.

A history of preceding attacks of pneumonia is common. Possibly, we may assume that the tumor caused obstructive atelectasis with pneumonitis resulting. The tumor, being so vascular, can change in size rapidly and succeeding attacks of atelectasis may follow.

Wheezing is frequently noted by the patient and has led to the diagnosis of asthma. Dyspnea may occur when the patient changes his position. If the tumor is on a long pedical it may shift its position and cause obstruction to a portion of the lung. This shifting may produce a wheeze in certain positions and not in others. Cough is quite constant.

Physical signs and x-ray findings may not be diagnostic, if the tumor has not reached a size which will obstruct the bronchus. However, the typical hemoptysis together with the other signs discussed above, should make one consider a diagnostic bronchoscopy. When the diagnosis can be established before the development of severe lung damage, due to chronic bronchial obstruction, a much better result can be obtained.

If the condition is unrecognized and untreated, obstruction of a bronchus will eventually occur. This means atelectasis, recurring pneumonitis, bronchiectasis, abscess or at times pyothorax. Bronchial obstruction is a definite indication for bronchoscopy, for both diagnosis and treatment.

Treatment consists of removing the tumor. If possible, this should be done through the bronchoscope. Punch forceps may produce considerable bleeding though electrocoagulation will help control this. A preliminary pneumothorax has been advised by some as a method of preventing blood from reaching the alveoli and causing aspiration pneumonia. Too vigorous cauterization may cause scar formation with stenosis of the bronchus resulting.

Radium applied locally or deep x-ray therapy have been used.

Surgical extirpation may be necessary particularly when the tumor has been long unrecognized and advanced pulmonary suppuration has resulted.

Case Report

Mr. R. B. H., aged twenty-seven, a conductor on the Northern Pacific Railroad, was referred to me by Dr. A. W. Ide, November 29, 1939.

The family history is negative.

The past history reveals that he has had two attacks of pneumonia, one in 1931 and the other in 1932. He coughed a little blood at this time. Following this, numerous telangiectatic areas appeared on his face and lips.

In April, 1934, he had a sudden attack of hemoptysis which cleared up rapidly. He was observed in the

Northern Pacific hospital and tuberculosis ruled out. The hemoptysis was considered to be from a bronchial varix—similar to those present in his mouth, cheeks, and lips.

In 1935, he coughed up a half glass of blood in three days, without fever or weight loss.

In May, 1939, a similar attack occurred, but the cough was worse and persisted. He raised yellow material until November, 1939, when he coughed up blood from four to five days—as much as a third of a tumbler full at a time. He now noticed a wheeze and a flapping noise when he coughed, which he localized on the right side. He was sent to the Northern Pacific Hospital in Saint Paul, for a bronchoscopic examination.

The chest radiograph gave negative findings.

The chest physical examination was negative except for the wheeze. His blood was normal. Blood pressure and urine were also negative.

Bronchoscopic examination: Blood was seen coming through the glottis and in the trachea. A tumor was seen in the right main bronchus. It bled very freely following the taking of a specimen for biopsy.

A diagnosis of benign adenoma was made by Dr. E. T. Bell.

On December 15, 1939, the tumor was completely removed by punch forceps and the base cauterized with 25 per cent silver nitrate.

The tumor was attached just to the right of the carina and was lying in the right main bronchus. It was about one and one-half centimeters in diameter.

Dr. Beach of Tacoma has written that he has seen the patient recently and he has had no recurrence of the hemoptysis and feels perfectly well.

Pathologists are not all agreed that this tumor is always benign.

A history of the recurring characteristic hemoptysis, wheeze, cough, together with the physical signs, x-ray findings, and bronchoscopic appearance should make an early diagnosis possible.

Bronchoscopic removal has resulted in many cures.

Discussion

DR. EDWARD D. CHURCHILL, Boston (by invitation): It is very kind of you to call on me and I wish I had more to add to this beautiful presentation by Dr. Phelps concerning this peculiar tumor. I can't add anything about its true nature and the pathologists and microscopists I work with are unable to solve the problem. They are puzzled concerning the histogenesis.

I suggested the idea of fetal lung rest to the pathologists but they do not agree with it. At the moment, Dr. Mallory thinks the tumor is more like the carcinoid that occurs in the intestine than any other neoplasm he knows about, yet he cannot demonstrate silver staining elements. Drs. Graham and Womak believe adenomas should be classified as so-called mixed tumors of the lung. Our pathologists do not agree with that. In San Francisco, Brunn and Goldman are drawing an analogy between this tumor and mixed tumors of the salivary glands.

I do not feel that these tumors are malignant in the sense that they are apt to metastasize or recur. They may show some cellular invasion of the surrounding lung, but we know that carcinoid tumors in the intestine may even show involvement of the adjacent lymph nodes and yet may exist for years without growth or spread.

The histories that Dr. Phelps gave are perfectly typical. It seems to me the importance of this tumor at the moment lies in putting it in a separate group from bronchogenic carcinoma. I don't care what it is called, so long as it is not confused with bronchogenic car-

cinoma. To do so will cloud the results of surgery and radiation therapy in carcinoma and they are already clouded enough now. The first adenoma I ran across I took out and reported it in the literature as carcinoma and have been busy retracting it ever since. Chevalier Jackson reported permanent arrest of a carcinoma removed through the bronchoscope; but his son, Dr. C. L. Jackson, has reviewed the case and believes it was an adenoma.

We find if we take the microscopically proven cases of cancer and the microscopically proven cases of adenoma, the proportion is about one adenoma to ten bronchial cancers. Now, if the many cancers that are not proven microscopically are included, it is probable that one out of twenty bronchogenic neoplasms will be an adenoma. But if we take the *respectable* bronchogenic tumors including cancer of the lungs, the tumors we can and have done something about surgically, these tumors make up about 25 per cent of the group. If I want to say adenomas are cancer, I can change my statistics about 25 per cent toward the better side because these patients, barring operative accident, are going to get well.

The only solution is to establish, as was done in bone sarcoma, a central tumor registry. The Association of Thoracic Surgery is working on such a plan. Adenomas may present themselves in the most bizarre way. The most striking case we have seen was a patient admitted to the hospital in coma because of veronal poisoning. He had taken veronal for sciatic pain. There were cough and hemoptysis, and the obvious diagnosis was cancer of the lung with metastases to the spine. He was ultimately discharged after lobectomy for adenoma of the bronchus and extirpation of a ruptured intervertebral disc, and is back at work. Neither diagnosis would have been possible ten years ago.

DR. JOHN F. NOBLE, Saint Paul: Speaking from the standpoint of pathologists, rather early in the game we made mistakes in the diagnoses of carcinoma of the lung. These mistakes have been made on cases of adenoma of the bronchus similar to the one just presented by Dr. Phelps. I think now, however, we have come to be able to spot these tumors at autopsy and perhaps at biopsy. I think the case just presented by Dr. Phelps is undoubtedly one of adenoma of the bronchus. The problem of diagnosis of carcinoma of the lung by biopsy is an extremely difficult one. So far, we have been fortunate in our experience in dealing with small biopsies of the bronchus and no serious errors have been made. Because of the extremely small size of the tissue submitted for examination, it is possible to have metaplasia of such a degree that a mistaken diagnosis of malignancy might be made.

We had at the Ancker Hospital a girl in her early twenties on whom I made a diagnosis of carcinoma of the lung. At that time she was extremely ill with pulmonary sepsis but following the biopsy her pulmonary infection improved and she was able to return to work. She was not seen again for eighteen months when she was examined by another physician. She was a picture of health, and the x-ray films of the chest showed a marked clearing of the atelectasis. The patient was presented at another hospital staff meeting, and I was fearful that a serious error had been made. After the patient was sent from the room, however, the physician admitted that the patient had again lost ten to fifteen pounds from her top weight, and that she was showing x-ray evidence of recurring atelectasis. The last of that story is not told, but I feel certain that the patient has a carcinoma of the lung.

Sooner or later, however, errors of diagnosis on biopsies of the bronchus are bound to be made because of the character of the material submitted for examination. I think that an accurate diagnosis of the tumors of the bronchus by biopsy depends upon an extremely close relationship between the surgeon, the bronchoscopist, and the pathologist.

Dr. E. M. Hammes, Saint Paul, gave the following case report and presented the patient.

THE SCALENUS SYNDROME: BRACHIAL PLEXUS NEURITIS

E. M. HAMMES, M.D.

Saint Paul

A unilateral brachial plexus syndrome of non-traumatic origin always presents an interesting diagnostic problem. Enlarged cervical ribs, metastatic involvement of the cervical vertebrae, hypertrophic arthritis of the spine, cervical hypertrophic pachymeningitis due to syphilis, syringomyelia, cord tumor, are among the possible etiologic factors. The typical syndrome of an elongated cervical rib is frequently encountered. It usually begins in middle adult life, with a heavy dragging sensation in the shoulder, pain over the deltoid extending down the arm, with weakness of the musculature, some atrophy of the intrinsic hand muscles with sensory disturbances, especially in relation to the ulnar nerve, with a slow progressive course until the extremity becomes practically useless. Associated with this may be other trophic changes, vasomotor disturbances, and a difference in the blood pressure of the two sides. Roentgenologic studies reveal an elongated cervical rib as the causative factor. Occasionally, this symptom group is encountered in patients in whom x-ray studies do not reveal a cervical rib. Naffziger and Grant, in the journal, *Surgery, Gynecology and Obstetrics*, December, 1938, report eighteen such cases and suggest the term "Scalenus Syndrome." In the literature to that date, fifty-one similar cases have been reported. The authors believe that, "the etiology consists largely in anatomical and developmental factors that result in an abnormal position of the shoulder girdle in relation to the thoracic cage. Embryologically, a postfixed brachial plexus is more readily subjected to tension and angulation in its course over the first rib and behind the anterior scalenus muscle. Injury, excessive occupational strain, or poor musculature, may cause the shoulder to droop and precipitate the signs and symptoms."

Myotomy of the scalenus muscle frequently produces excellent results, even in long-standing cases.

Case Report

This patient presented four outstanding symptoms:

1. Slow progressive weakness of the left arm with atrophy of some of the intrinsic hand muscles.
2. Pain and tenderness in the left supraclavicular space extending down the arm and hand.
3. Sensation in the left side of the neck as if "cords were tight and short."
4. At times, the left arm feels full and swollen, especially when she is lying down. This sensation disappears when the arm is elevated and a feeling develops as if blood were rushing into the arm.

The patient is a female, aged forty-two, who was referred to us by Dr. F. V. Langenderfer on February 19, 1940.

Her family and personal history were negative except that her right hand is deformed due to a burn at the age of eighteen months. Because of this, she per-

forms most of her heavy work with the left hand, such as husking corn, carrying heavy milk cans, and other farm work.

Her present complaint began in 1931, nine years ago. At that time she noticed numbness, pain, paresthesia, and weakness of the left thumb. This continued for three months, then disappeared completely for six months. The condition recurred and also involved the palmar surface of the second and third fingers. The pain gradually extended up the extensor surface of the entire arm to the tip of the shoulder, and the entire arm tired easily. This continued for four years. She then developed a sensation as if the cords in the left side of the neck were too short and tight. The muscles around the left thumb began to waste and the weakness in the arm became more pronounced. These symptoms continued off and on until October, 1939, when they became more pronounced. She now is unable to pick up objects with her left hand, to button her clothes, or do any heavy work. The pain is more pronounced. The arm feels big and swollen, especially after she goes to bed and is quiet. When she moves it about or elevates it, she has a sensation as if blood were rushing into it.

The physical examination was negative except for a deformed right hand.

The neurologic examination is negative except for her left arm. Pupils, fundi, eye movements, and other cranial nerves are normal. The right upper extremity is normal throughout. The left upper extremity possessed normal muscle strength in the left upper arm with apparent weakness because she said it pained in the elbow when she held the arm against resistance. Movements at the wrist were good. The biceps, triceps, and perist reflexes are normal. She had atrophy of the thenar, adductor pollicis, and slight atrophy of the interossei muscles in the left hand. The grip, with the dynamometer, in the left hand was 42. We were unable to test the right hand because of the deformity. Sensation was normal over the entire left arm to the wrist. From the wrist down on the palmar surface of the hand, including the inner portion of the thumb, pain and tactile sense were impaired. On the dorsal surface of the hand sensation was normal except over the distal phalanges of the first three fingers where touch and pain sense were impaired. She had marked tenderness in the left supraclavicular region and over the entire left arm, but there was no definite nerve-trunk tenderness.

Her hemoglobin is 80 per cent; blood pressure, left arm 126/74, right arm 124/76; urine normal. The blood Wassermann reaction was negative.

The spinal fluid was clear and 6 c.c. were removed. The pressure was 180 mm. of water, which rose promptly to 350 with jugular compression, with prompt return to 180 when the pressure was released. It contained one cell, a trace of globulin, a negative Wassermann, a negative colloidal gold curve, 1111100000, and quantitative protein 30 mgms.

X-ray examination of the cervical spine and the left shoulder region was negative. There was no evidence of cervical rib or arthritis.

A diagnosis of scalenus syndrome was made and a myotomy of the scalenus muscle will be done next week.

* * *

Addenda: This patient was operated on by Dr. W. C. Carroll at St. Joseph's Hospital, on March 26, 1940. The left scalenus anticus muscle was markedly hypertrophied and tense, and was severed. Within forty-eight hours the patient stated that the pain in the shoulder and arm had definitely improved, and the fullness and congested feeling have subsided. She should make a complete recovery.

SARCOMA OF THE ULNA; LATE RESULTS

ARNOLD SCHWYZER, M.D.
Saint Paul

Dr. Schwyzer reported a case of swelling of the lower end of the right ulna which proved to be giant cell sarcoma. Resection of the ulna in June, 1916, and insertion of a piece of tibia. Late results reported. Movements free, arm strong, no complaint. Radiographs show good transformation of the transplant into tubular bone. Full report of the case will be given later.

CONGENITAL HEMOLYTIC ANEMIA WITH SPLENECTOMY

Case Report

MARTIN NORDLAND, M.D.
Minneapolis

Congenital hemolytic anemia is a chronic, hereditary disorder in which blood destruction over-balances blood formation, with resultant icterus, anemia and splenomegaly. It is generally agreed that heredity plays a great part in the etiology, most of the cases being inherited according to Mendelian law, and that the increased blood destruction is dependent upon increased fragility of the red blood cells. It has been observed, however, that in a number of mild cases the fragility test was normal.

The case report here submitted is that of a white, unmarried female, forty-four years of age, admitted to the hospital on September 12, 1939. Her presenting complaints were: (1) intermittent attacks of jaundice for the past twenty years; (2) intermittent spells of anemia for the same period; (3) severe upper right quadrant pain for ten days prior to admission to the hospital; (4) irregular spells of digestive distress associated with ingestion of fatty foods; and (5) recent complaints of frequency, nocturia, and some dysuria.

The patient had a thyroidectomy with uneventful recovery in 1937. The past history otherwise was negative except as stated above.

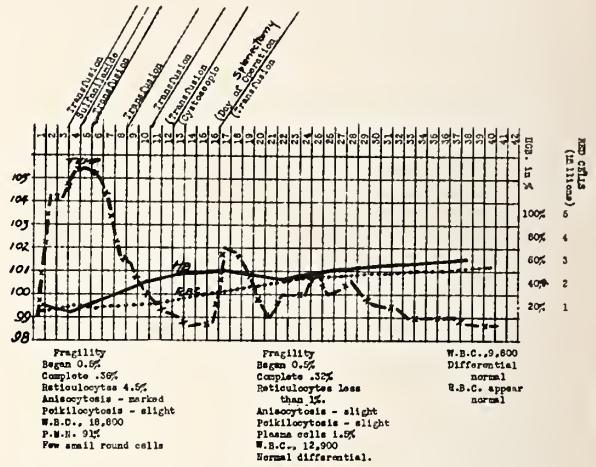

Physical examination of the patient revealed a fairly well-nourished, well-developed, white, but icteric appearing female of about the stated age, who was not in acute distress. Her sclerae were icteric and the pupils reacted to light and accommodation. The throat was clear but the mucosa was yellowish tinged. The lungs and heart were normal. The blood pressure was 128/68. Abdominal examination revealed no unusual tenderness, the liver was not palpated, but the spleen was felt four fingers (8 cm.) below the costal margin in the left mid-axillary line.

Blood examinations on admission showed a hemoglobin of 32 per cent, red blood cells 1,610,000, with a majority of spherical microcytes. There was a color index of 1.1 and a reticulocyte count of 4.5 per cent. Fragility was increased by 25 per cent.

Because of the history and the findings recorded above, a diagnosis of congenital hemolytic anemia with jaundice and an associated cholelithiasis was made.

However, the situation suddenly became serious and confusing. Two days after admission the patient's temperature jumped to 104° and for six days the temperature fluctuated rapidly between 99° and 105.6°. A catheterized specimen of urine was found to be loaded with pus cells. Albumen was present 2 plus. There were a few r.b.c., and a culture of this urine showed *B. coli*. The hemoglobin which was recorded 32 per cent on admission, September 12, 1939, had dropped to 26 per cent by September 16 (Fig. 1). On

cystoscopic examination, September 23, 1939 (11th day) the patient was found to have a marked cystitis with the kidneys apparently free from pus, but culture showed *B. alkaligenes*. From roentgenological ex-

HEMOLYTIC JAUNDICE WITH ANEMIA
PYLOREPTICUS OF ADMITTANCE

Fig. 1.

amination, following the retrograde pyelography, the following conclusions were drawn: enlargement of the right kidney with normal renal pelvis, marked enlargement of the liver and spleen with the enlarged spleen pushing the kidney down and medialward and thus distorting the pelvis. There were also multiple calcified gallstones (Fig. 2).

The patient was placed on a regime of multiple transfusions of citrated blood. In spite of the low hemoglobin (25 per cent) and the jaundice, the patient was given sulfanilamide by Dr. Ulrich. This therapy was followed by marked improvement and within four days the temperature had become normal, the pus had disappeared from the urine and the hemoglobin was elevated to 49 per cent.

By September 28, 1939 (16 days after admission) the patient was physically fit for splenectomy, which was then considered the treatment of choice. Five hundred c.c. of citrated blood was administered to the patient preceding the operation. Under gas and ether anesthesia, a splenectomy was performed. The spleen was found to be widely attached to the cardiac portion of the stomach, the splenic flexure of the colon and to the diaphragm. This caused considerable trouble in its removal. To assist in the displacement of the spleen, the table was sharply tilted so that the head was considerably higher than the feet. Fifteen minims of epinephrin was injected into the splenic artery immediately preceding the application of the ligature to this vessel. Application of the ligature to the splenic vein was delayed about 60 seconds to permit thorough emptying of the blood contained in the spleen into the general circulation. Four transfusions of 500 c.c. each of citrated blood were given on alternate days following the operation.

The spleen was 23 cm. in length and 16 cm. in diameter following excision (Fig. 3). Its shape was normal; weight was 1,450 grams. On cut surface it was chocolate-colored and firm without much free blood. The corpuscles were somewhat less numerous and less distinct than in the normal and on microscopic section there were marked numbers of erythrocytes throughout the spleen with a reduction in number of splenic corpuscles. On the 25th postoperative day the patient was discharged from the hospital.

Laboratory findings showed hemoglobin 65 per cent, r.b.c. 2,950,000 per cm., color index 1 plus, reticulocytes less than 1 per cent, and the fragility of the erythrocytes apparently unchanged.

Fig. 2.

The correct diagnosis in almost all cases of congenital hemolytic jaundice should be made by the presence of icterus with splenomegaly, associated anemia, increase in the number of polychromatophilic red cells and reticulocytes, and increased fragility. Most mistakes are made in the mild cases. Splenectomy is quickly beneficial in the severe cases; relief of symptoms is usually permanent. The operative mortality is variable in different clinics but should not be high. There is a rapid postoperative return of the red count to normal because of the speedy regeneration of the red blood cells. Occasional cases may require cholecystectomy as well.

Discussion

DR. H. L. ULRICH, Minneapolis: There are several items which could be stressed in this case. It is not a glaring mistake to make a diagnosis of cholecystitis in the presence of hemolytic jaundice. Sixty per cent of the cases present this complication. A bedside diagnosis could be made on this patient with the physical findings and history. The urgent thing, she was so very ill. Urinary antiseptics had been given. A transfusion had not made any difference. In fact, these cases do not take transfusions very well. Having seen a report of a case of neutropenia with sepsis which responded to sulfanilamide, we thought we would use it for her bladder infection. Her hemoglobin was at its lowest and the temperature was at the highest. Giving sulfanilamide to a patient with a hemoglobin of 28 per

cent is a rather drastic procedure. Then there was her jaundice. The liver was under pressure trying to excrete the enormous amount of bilirubin being delivered to it. Liver insufficiency is another contraindica-

Fig. 3.

tion in the use of sulfanilamide. We were traveling on thin ice. But the response was most favorable. Her urine cleared up. Her temperature came down and her hemoglobin and reds began to rise.

We did not see the spleen contract at the time of the operation when adrenalin was injected into the splenic artery. It may have been that we did not wait long enough or it may have been due to the extensive adhesions of the splenic capsule. No blood examination was made before or just after the adrenalin injection. The cholelithiasis and cholecystitis can be taken care of when this patient has rehabilitated her blood following the splenectomy.

MULTIPLE TUMORS OF THE TESTICLE

GILBERT THOMAS, M.D.

Minneapolis

Dr. Thomas gave a report on the above subject.

Discussion

DR. J. C. LITZENBERG, Minneapolis: I would like to ask Dr. Thomas one or two questions. In testicular tumors, have you any figures to show the percentage that gave the positive hormone test for chorion epithelioma?

DR. THOMAS: No, I haven't. I have a report now on my desk, by a urologist in New York. In this paper the doctor describes the chorion epithelioma but does not include a complete bibliography.

DR. LITZENBERG: Theoretically, one should not get a positive hormone test unless there is chorion epithelioma present. If the prolan test is positive, chorion epithelioma must be present.

DR. H. L. ULRICH, Minneapolis: Some years ago (it was when Dr. Berglund was with us) we had a patient—a young man—in the University Hospital, who had numerous cysts of the lung. There was a good deal of speculation regarding these growths. It was not until some one pulled down his bed clothing and examined his testicles that it was noticed he had a teratoma on one of them. This explained the origin of the cysts very conclusively.

The meeting adjourned.

A. G. SCHULZE, M.D., *Secretary.*

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

COMPENDIUM OF REGIONAL DIAGNOSIS IN LESIONS OF THE BRAIN AND SPINAL CORD. 11th Edition. Robert Bing, Professor of Neurology, University of Basel, Switzerland. Translated and edited by Webb Haymaker, Assistant Clinical Professor of Neurology and Lecturer in Neuro-Anatomy, University of California. 292 pages. Illus. Price, \$5.00, cloth. St. Louis: C. V. Mosby Co., 1940.

CANCER IN CHILDHOOD and a Discussion of Certain Benign Tumors. Harold W. Dargeon, M.D., F.A.A.P. Attending Pediatrician, Memorial Hospital for Cancer and Allied Diseases, New York; Associate Pediatrician St. Luke's Hospital, New York; Associate Pediatrician New York Foundling Hospital; Instructor in Pediatrics, College of Physician & Surgeons, Columbia University. 114 pages. Illus. Price, \$3.00, cloth. St. Louis: C. V. Mosby Co., 1940.

INTRODUCTION TO MEDICINE. Don C. Sutton, M.S., M.D. Associate Professor of Medicine, Northwestern University School of Medicine; Attending Physician, Medical Division of Cook County Hospital; Chief of Cardiac Clinic, Cook County Hospital, Chicago; Attending Physician, Evanston Hospital. 642 pages. Illus. Price, \$3.25, cloth. St. Louis: C. V. Mosby Co., 1940.

CHEMOTHERAPY AND SERUM THERAPY OF PNEUMONIA. Frederick T. Lord, M.D., Clinical Professor of Medicine, Emeritus, Harvard Medical School; Member of Board of Consultation, Massachusetts General Hospital; Elliott S. Robinson, M.D., Ph.D., Director Division of Biologic Laboratories, Massachusetts Department of Public Health; Roderick Heffron, M.D., Medical Associate, the Commonwealth Fund; Formerly Field Director Pneumonia Study and Service, Massachusetts Department of Public Health. 174 pages. Illus. Price, \$1.00, cloth. New York: Commonwealth Fund, 1940.

LET'S TALK ABOUT YOUR BABY. H. Kent Tenney, Jr., M.D., F.A.A.P. Associate Professor of Pediatrics, University of Wisconsin Medical School, Associate Pediatrician to State of Wisconsin General Hospital. 115 pages. Illus. Price, \$1.00, cloth. Minneapolis: University of Minnesota Press, 1940.

SYNOPSIS OF OBSTETRICS. Jennings C. Litzenberg, M.D., F.A.C.S. Professor Emeritus of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis. 394 pages. Illus. Price, \$4.50, flexible binding. St. Louis: C. V. Mosby Co., 1940.

THE KOSHER CODE of the Orthodox Jew: Being a literal translation of that portion of the sixteenth century codification of the Babylonian Talmud which describes such deficiencies as render animals unfit for food (Hilkot, Terefot, Sulhan Aruk); to which is appended a discussion of Talmudic anatomy in the light of the science of its day and of the present time. By S. I. Levin, Senior Rabbi of Minneapolis and Edward A. Boyden, Professor of Anatomy, University of Minnesota. Cloth. Price \$4.50. 243 pages. Illus. Minneapolis: The University of Minnesota Press, 1940.

The subtitle tells exactly what this book consists of in its scope and purposes. It is a work of great historical and scientific value; one which may be read with

interest and profit by all who seek to be better informed about the close intertwining of the development of religion and medicine. How Dr. Boyden came to become interested in this particular phase of the subject is told by him in the preface. It was when he was engaged in examining some ten thousand vertebrate livers in the abattoirs of Boston that he met "kosher cutters" from the local synagogues, who told him that such anomalies as he was seeking could be found described in the latest codification of the Babylonian Talmud, published in Venice in 1564. This greatly aroused his curiosity and he spared no effort to "follow through" and secure authentic information, all of which confirmed what he had been told and finally resulted in this masterly piece of collaboration with Rabbi Levin.

More than most languages, the Hebrew and the Amharic contain many words which have a double meaning and many somewhat similar words which have exactly opposite meanings. This reviewer knows of many instances, for example, in the Old Testament where failure on the part of the translators to appreciate this has caused many errors to creep in and change the whole meaning of the context. In the present instance the translators have exerted every effort to preserve the literal meaning of every word, often very difficult for the reasons given and for the further one that sometimes there is no adequate equivalent in English. The result is an excellent piece of work, for the completion of which we congratulate both of the scholarly translators and annotators in what must have been a most exacting task.

GILBERT COTTAM, M.D.

SKETCHES IN PSYCHOSOMATIC MEDICINE. Smith Ely Jelliffe, M.D., New York. 155 pages, including an index. Price \$3.00. New York: Nervous and Mental Disease Monographs (64 W. 56th Street), 1939.

This small book consists of a series of reprints and addresses given by the author at various times. The style is discursive and the language may be somewhat confusing to those not familiar with psychoanalytic terms. An indication of the style is found in Dr. Jelliffe's own comment: "As a matter of history I can recall a comment once made by my brother who, listening to me talk when a young man, said that he often held his breath wondering if I would come out all right in my sentence before I got through."

The writer attempts a broad approach to medical problems from the viewpoint of evolution and psychoanalysis. He searches for the meaning, in a general and philosophical way, of human ailments. For example: "Any deviation from Object or Aim (in the Unconscious) is capable of causing disorder or disaster in the delivery of the energy of the human being either at the level of metabolism or at the level of conduct, or both. At the conduct level such disorders or disasters are of social significance chiefly and are dealt with chiefly by legal agencies as antisocial, criminal or delinquent conduct, or by medicine as psychoses and certain psychoneuroses. At the metabolism level, organ disturbances result."

An idea of the contents of the book may be obtained by glancing over the chapter headings.

I. What Price Healing?

The author points out the necessity for concomitant psychotherapy along with surgical treatment of some ailments.

II. Psychopathology and Organic Disease

Any deviation from object or aim threatens the harmonious action patterns within the machine.

III. The Death Instinct in Pathology

The author attempts to explain in Freudian terminology, recovery from mental illnesses following severe somatic illnesses or severe operations.

IV. Dupuytren's Contracture

This chapter contains an interesting historical account of Dupuytren's contracture. The author attempts to point out the significance of "strong grasping tendencies."

V. The Psyche and the Vegetative Nervous System

This is an attempt to evaluate the significance of mental factors in the endocrine disorders, especially hyperthyroidism.

VI. Bodily Organs and Psychopathology

This chapter contains an interesting brief developmental history of psychoanalytic psychiatry.

VII. The Skin, Nervous System and the Bath

This skin is discussed from the evolutionary standpoint, starting with the ameba. Eczema and psoriasis are given most attention.

VIII. Neuropathology of Bone Disease

The author reports a case which is supposed to show the relationship of emotional tension, due to unconscious motivation and development of a giant cell tumor of the lower end of the tibia.

IX. Psychoanalysis and Myopia

This chapter is a discussion of the psychological meaning of the development of myopia in the adolescent.

X. The Ecological Principle in Medicine

This is a brief dissertation on "the adaption of man as a whole to the whole of the cosmos."

The author defines the Neo-Hippocratic physician as one who is not satisfied with the chemical explanation alone, nor biologic nor purely psychologic, but searches for all three. If one has the time and wishes to use it for close study of the material in this book, he is almost certain to increase his breadth of vision in psychosomatic medicine. The problems raised are of great interest and the author's contentions are engaging, but they suffer from lack of genuine proof and close reasoning.

ALEX BLUMSTEIN, M.D.

FUNCTIONAL DISORDERS OF THE FOOT; THEIR DIAGNOSIS AND TREATMENT. Frank D. Dickson, M.D., and Rex L. Diveley, M.D. 305 p. Illus. \$5.00. Philadelphia: J. B. Lippincott Co., 1939.

This book is one which every practicing physician should own. Painful feet are a cause of so much dis-

SILVER PICRATE

Wyeth

HAS SHOWN A CONVINCING RECORD* OF EFFECTIVENESS IN ACUTE ANTERIOR URETHRITIS

due to *Neisseria gonorrhoeae* • *Trichomonas vaginalis*
Monilia albicans

Silver Picrate is a crystalline compound of silver in definite chemical combination with picric acid. Dosage form for use in anterior urethritis: Wyeth's Silver Picrate Crystals in an aqueous solution of 0.5 percent.

Supplied at all pharmacies in vials of 2 grams

Complete literature on Silver Picrate as used in genitourinary and gynecological practice will be mailed on request.

*"Treatment of Acute Anterior Urethritis with Silver Picrate," Knight and Shelanski, *AMERICAN JOURNAL OF SYPHILIS, GONORRHEA AND VENEREAL DISEASES*, Vol. 23, No. 2, pages 201-206, March, 1939.

JOHN WYETH & BROTHER, INCORPORATED, PHILADELPHIA, PA.

ability and the complaint is so common that there are few doctors who are not consulted almost daily by their patients for this reason. Without going into the evolution, anatomy and physiology of the feet more than is necessary for an intelligent approach to the more practical side of functional disorders, the authors give enough of these subjects to allow the general practitioner who uses the book to handle many of his cases without requiring orthopedic consultation.

The subjects of imbalance and of proper shoeing are so adequately covered that a full understanding of these chapters will allow one to treat with confidence the large majority of cases seeking relief. The less common ailments are also thoroughly covered and their discussion rounds out a book which is certainly an outstanding one on the subjects treated. It can be unqualifiedly recommended to anyone with an interest in foot disorders.

WALLACE H. COLE, M.D.

SHOCK. BLOOD STUDIES AS A GUIDE TO THERAPY. John Scudder, M.D., Med. Sc.D., F.A.C.S. 315 pages. 55 illustrations. 5 plates (3 in color). Philadelphia: J. B. Lippincott Co., 1939.

This book is primarily concerned with the results of a new treatment of shock. It brings out the importance of potassium in the etiology of shock and emphasizes the blood changes which take place in this state. It presents the different theories of shock and also the present-day types of treatment of this condition. This portion is a beautifully condensed summary of the different methods of treatment and an evaluation of them. The author then presents in detail experiments illustrating hemo-concentration and changes in potassium in experimental shock. He stresses the importance of the determination of cell volume, specific gravity of whole blood, specific gravity of plasma, amount of plasma proteins and includes as a supplement a concise laboratory manual for determination of this data. He then includes detailed blood studies in 28 cases of post-operative shock, shock due to trauma alone, shock due to trauma complicated with hemorrhage, shock due to hemorrhage, shock due to burn, shock due to perforated duodenal ulcer and primary shock. Treatment with suprarenal cortex is then discussed. He includes at the end three historical and chronological sketches on developments in the conception and treatment of shock, developments in the physiological and toxicologic effects of potassium and developments in some of the functions of the adrenal glands.

The bibliography contains 533 references. A very interesting feature is the insertion of blank pages at various points for additional notes of the reader.

Although this book contains a great deal of experi-

mental data, which might prove somewhat laborious for the casual reader, the résumé of the whole subject of shock is so concise and informative that it is well worth a close study. It will prove of value not only to those interested in the experimental side of shock but also to those who are of necessity more interested in the practical side.

WALLACE P. RITCHIE, M.D.

ELECTROCARDIOGRAPHIC PATTERNS — THEIR DIAGNOSTIC AND CLINICAL SIGNIFICANCE. Arlie F. Barnes, M.D., The Mayo Clinic, Rochester, Minnesota. 197 pages. Illus. Price \$5.00. Springfield, Illinois: Charles C. Thomas, 1939.

The voluminous contributions to the current literature of recent years on electrocardiographic changes incident to myocardial effects associated with many clinical conditions has made welcome Dr. Barnes' monograph. No attempt is made to discuss the fundamentals of electrocardiography on the subject of arrhythmias which have been amply covered by previous publications. However, in this treatise the author has brought together in an orderly fashion, well illustrated, the significant contributions to this field, many of which are the results of his own investigations.

The combinations of alteration from the normal of the contours, voltage and time relations of the usual electrocardiographic leads are designated as patterns. These patterns have been described as quite definite indications of the presence of certain clinical conditions. Most important of these is coronary vascular occlusion, the patterns of which are well described in both the acute and chronic forms. Of particular interest are the author's descriptions of the patterns seen in conditions putting undue strain on one or the other ventricle, and his evidence indicating that they are due to metabolic factors incident to the strain rather than actually demonstrable changes in the myocardium.

The descriptions of the patterns seen in pericarditis and the effects of various drugs, metabolic disorders and infections on the electrocardiogram are especially important in that they call attention to the fact that such changes can occur. They show how the records may lead to consideration of these conditions, otherwise unsuspected.

It is unfortunate that the illustrations of the fourth lead could not be given as taken with the technic recommended by the Committee for the Standardization of Precordial Leads. This cannot be regarded as a serious criticism, but rather the penalty any monograph must pay in presenting a subject in which knowledge is advancing so rapidly.

No. 6

ORGANIZED MEDICINE AND INDUSTRIAL HEALTH*

C. M. PETERSON, M.D.

Secretary, Council on Industrial Health
American Medical Association
Chicago, Illinois

MEDICAL interest in the effects of occupation and environment on health has existed for a very long time. Yet only occasional efforts at improvement took place in this country until about thirty years ago when new concepts regarding responsibility for health conservation among industrial workers began to exert very profound influences upon industry and upon the medical profession. The first in importance was the enactment of workmen's compensation legislation. Once a monetary value was placed on disability arising out of or in the course of employment, it did not take industry long to realize that industrial accidents and occupational disorders are to a very considerable degree preventable. Furthermore, it has been repeatedly demonstrated that health maintenance and proper working environment applied to the worker have very definite favorable effects on rates of industrial production. It is upon considerations such as these that our modern interest in industrial health fundamentally rests.

The private practitioner of medicine, specialist or not, provides 80 per cent of the medical service which industry supplies to its workers either because of statutory requirements or for other reasons. Almost without exception he has confined his industrial activity to case work remedial in nature. It is interesting to classify some of the reasons why the private physician has failed to participate in the fuller aspects of accident and disease prevention and the promotion of health programs among industrial workers, activities which have appealed to and been undertaken by so many extra-professional

agencies. The simplest explanation is that this attitude proceeds naturally from the way industrial medicine and surgery have developed. At the outset, interest was almost entirely concentrated on individual problems of surgical repair and rehabilitation. Likewise, medical education has, in the opinion of many commentators, not been at all helpful in developing a real appreciation of the effects of occupation on physical welfare and the best means for improvement. The greater emphasis on individualized study and management of the sick patient has prevented the assignment of attention to the principles of health conservation of groups and the recognition and arrest of incipient diseases which constitute to a very considerable extent the principal motivations behind the whole field of industrial health. There has also been intentional lack of coöperation on the part of many physicians arising out of their real concern that adequate standards of medical practice could not successfully be transferred into the industrial picture because of industry's unwillingness or inability to support them. Physicians have also had other unfortunate relationships with industrial medicine, characterized by lack of essential qualifications on the part of many who have undertaken this type of activity, its not infrequent status as exploited dispensary work under conditions where the "company doctor" attitude is too prominently interpreted as the proper function of an industrial medical service, and the methods used by some physicians to compete unfairly not only in industrial practice but in private practice through industrial connections. Another large contributor to dissatisfaction with certain features of industrial health has been discontent

*Read at the County Officers' Meeting, Saint Paul, Minnesota, February 24, 1940.

with certain characteristics of workmen's compensation administration, largely centering in absence of qualified medical representation in compensation administration, the illogical limitations both as to time and cost which have been set up in relation to medical and hospital care for industrial disability and in respect to free choice of physician.

Need for Medical Interest in Industrial Health

In spite of these unsatisfactory experiences, organized medicine has good reason to believe that industrial health is an important and rapidly expanding province of special medical interest, both in respect to preventive medical practice and public health administration. This opinion is based on the following considerations: There are approximately fifty million gainfully employed workers in the United States, ten years of age or over, who engage in some nine hundred occupations potentially hazardous to health. A great many, but by no means all, of these hazards are concentrated in manufacturing plants and in those enterprises devoted to the production and transportation of raw materials for the fabrication of manufactured goods. Conditions of employment have demonstrable effects on the productive and life spans of workers which, as has been shown, are most noticeable in unskilled occupational or socio-economic classifications. A great many, but not all, of the uncontrolled industrial health exposures exist in small plants which comprise a considerable majority of the industrial establishments in this country and in which the majority of workers are employed. Most of these small business enterprises are, or consider themselves to be, unable individually to support health programs beyond first aid and physicians on call who treat emergencies and compensable disability. In large plants industrial medical services are of demonstrated value in the reduction of compensation costs, the lowering of absenteeism, the lessening of labor turnover, and elevating the physical welfare of employees. On the average, each male employee can expect to lose approximately nine days of work annually, one day of which is due to accident, and a fraction of a day to occupational disease. The balance of lost time arises from illness not directly assignable to industry. The total cost annually of sickness and injury from all causes in industry is staggering and must be computed in the billions of dollars. Nonoccu-

pational health problems affecting as they do the regularity and continuity of working periods, together with the countless subnormal and pathological conditions uncovered through physical examination programs in industry, provide the private physician with an extensive opportunity to assist in the improvement of the physical welfare of employed groups.

Increased Demands on the Profession by Industry

There are two assumptions which can be drawn from this brief recital of the extent and nature of industrial health problems. The first is that demands made on all branches of the medical profession are much more likely to increase than otherwise. The other is that the time has come when the organized medical profession must manifest a constructive interest in the problems of industrial health, must realize their fundamental importance, and must actually do something about it or else relinquish leadership to industry. There are other even less attractive possibilities. This frame of mind is strengthened by the attitude of manufacturers' organizations, trade unions, insurance carriers, compensation agencies, and of the worker himself, all of whom are currently and actively engaged in establishing the economic, social and humanitarian values of control over industrial accidents and disease. If no other stimulus were provided, the extension of workmen's compensation benefits to occupational disease would be reason enough for the present widespread interest. But in addition, technical developments in industry give rise to health hazards multiplying so rapidly as to leave distinct gaps between recognition of the causative agency and the perfection of medical and engineering methods designed to cope with them. Progress will occur only as this lag is overcome by articulating available knowledge regarding occupational health exposures with the practicing medical profession, the industrial plant physician, and with the existing or developing agencies of industrial hygiene in state and local governments.

The Responsibility of Medical Organization

The Council on Industrial Health of the American Medical Association, therefore, believes that medical organization has a distinct obligation to safeguard the standards of medical service in industry both as to scope and to ade-

quacy. To accomplish these purposes it has implicit faith in medical self-discipline and education. We have as a consequence asked for and received in a little more than a year's time, co-operation from most of the medical associations in states where the concentration of industrial activity justifies the formation of coöperative committees on industrial health. A program has been suggested to these committees in the following terms which obviously must be adjusted to fit local circumstances:

1. To develop on the part of all physicians a good understanding of the proper functions of medical organizations in industry. These over and above required medical and surgical care are physical examination, maintenance of suitable records, the adoption and supervision of necessary control measures and the education of the employee to a personal interest in his own physical welfare.

2. To train physicians to recognize and report occupational diseases promptly.

3. To train industry and labor to the value of industrial health conservation.

4. To elevate medical standards under workmen's compensation.

5. To scrutinize all social legislation affecting the health of industrial workers.

6. To clarify relationships between industrial and private practitioners.

7. To improve relationships between physicians and insurance carriers.

8. To establish working relationships with all state agencies interested in industrial health.

9. To extend as far as possible activities of this same description into county medical societies.

It has been a source of very considerable encouragement to observe that already certain of the county medical societies are beginning to organize committees on industrial health, in order to provide for proper leadership in their own communities respecting health measures designed for employed groups and in accordance with local needs. Some thirty such committees have already been formed. These developments are of fundamental importance since it must be conceded that it is in the county society where the acute problems of industrial practice are encountered and where they are most directly dealt with. Interesting contributions in the field of

industrial health have already been made by county societies, as for example, the outline of "Duties of a Contract Physician," by the Wayne County Medical Society, Michigan, the plan for the control of extravagant medical testimony developed in the Fulton County Medical Society, Georgia; and the emphasis placed upon the essentially public health function of the plant physician as formulated in certain counties in Michigan where such physicians are deputized as health officers.

Activities adopted by or suggested for committees on industrial health in county medical societies have been presented to the state committees. It is not expected that any county medical society will be in a position to launch a complete program as outlined. The recommendations are offered in some detail in order to present the proper appreciation of the scope of industrial health activity and to suggest one or more projects which the county associations might profitably engage in.

Certain of these activities fall in the field of investigation.

1. A county society committee should have clearly in mind all past actions of the society which refer in any way to industrial medical practice or health maintenance of employed groups.

2. It should establish an index or file of physicians specializing in or giving major attention to industrial practice together with their industrial connections and the scope of service they provide. Recent experiences of the Council indicate that such undertakings are not too difficult if attempted on a county basis and that the knowledge obtained may be extremely useful in defining proper industrial medical objectives.

3. It should establish as much familiarity as possible with the character of industrial operations in the county and the essential industrial health problems of each, whether primarily caused by accidents, by occupational diseases or non-industrial connected illnesses. Without some attention to the collection of such information, a clear idea of the extent of the industrial health problem in any community will be obtained with difficulty. Once the nature of the business is known, many publications will be helpful in determining potential occupational hazards.

4. The committee should survey the relation-

ships existing between the physician in industry and (1) employer; (2) employee; (3) private practitioners. It is hoped that shortly the Council may provide a statement on the essentials of industrial medical service which will serve as a common ground of agreement for all parties concerned.

5. It should direct a great deal of attention to the needs of the small plant and how the private practitioner can, under county society guidance, bring to such establishments the advantages of health maintenance through physical examinations, plant sanitation, control of hazardous materials and processes, and health education of workers. This is on all counts the greatest contribution the medical profession can make in the field of preventive medical practice. Certainly the field is almost unexplored and offers a sufficiently large number of individual health problems to keep a great number of physicians busy for years to come. To assist the medical profession in the development of such services, the Council has projected a series of articles on medical organization in industry.

Other activities fall under the heading of correlation.

1. The committee can list the other community organizations which have or ought to develop an interest in industrial health problems.

Contacts should be established with—

Local health departments.

Industrial and public health nursing organizations.

Safety and industrial engineers or organizations.

Local hospital council.

Social and welfare agencies, as for example, health associations, tuberculosis clinics, venereal disease control committees, etc.

Associations of Commerce or local manufacturers' associations.

Local labor council.

Casualty insurance adjustors and brokers.

Local bar association.

Adjudicating agencies—courts, compensation commissioners or medical representatives thereof, and arbitrators.

2. The committee should determine whether any of these agencies are in a position to con-

tribute to the physical betterment of the workers along lines which private practitioners might have difficulty in providing or which small plant owners might have difficulty in financing individually.

Most important is education. In respect to professional training, it has been suggested that county societies can:

1. Use their influence to improve undergraduate training in fundamentals of industrial health.

2. Attempt to develop an educational service through meetings of the county medical society based on knowledge gained of local occupational exposures.

3. Attempt to acquaint physicians with true relations between trauma and disease.

4. Educate the profession to the best available means for the early recognition of intoxications or other occupational diseases.

5. Inform the profession of the statutes requiring the reporting of occupational diseases and strongly urge full compliance.

6. Request the inclusion of industrial health training in postgraduate courses under state society sponsorship.

7. Investigate the desirability of a section on industrial health in the scientific assembly of the state medical association.

There will be excellent opportunities for non-professional education, such as

1. Assisting the industrial nurse to improve her status ethically and professionally.

2. Demonstrating to plant operators the value, both humanitarian and financial, of employee health maintenance.

3. Investigating the possibilities for bringing to the worker himself a sense of personal interest in his own physical welfare both inside and outside the working environment.

4. Acquainting the general public with accomplishments in industrial medical practice and the intention of the medical profession to elevate standards in this field.

I hope I have succeeded in impressing upon you the fact that much needs to be done by medical organization in the field of industrial health. I hope also that we can count on your sustained interest and coöperation.

THE DEFENSE OF INSANITY IN CRIMINAL CASES*

JAMES A. GARRITY

Attorney-at-Law

Moorhead, Minnesota

IN THE interest of public safety, your Association is to be commended for including in your deliberations, the question of the defense of insanity in criminal cases. You are a learned profession. You have the interest of humanity at heart. You see life from the beginning to the end, and you are so interwoven in the everyday affairs of man's life and the public good, that your findings and conclusions on the subject on which I have been called upon to address you, should be such as to receive an intelligent and responsive hearing.

Occasionally a criminal case in which the defense of insanity is raised, enters the courts of this state. It is a case in which the State is represented by the prosecutor. The defendant is represented by a member of the legal profession. In the course of the trial, members of your profession become important and convincing witnesses on both sides of the case. You are called upon to testify on behalf of the State, as well as on behalf of the defense. A lay jury must then weigh your expert testimony and return a verdict. When that verdict is returned and linked with events that follow, the public becomes aroused, ready as it always is to try to place blame on either the medical or the legal fraternity, or both, forgetting that in the long run it is the public represented by the jury that passes its final judgment, and must take the responsibility. I approach this subject not in a critical mood, or with any particular case in mind, but for the purposes of painting as it were, a picture of the facts and circumstances surrounding the subject, and then leaving it for such discussion as you find it deserves.

The County Attorneys' Association of the State, of which I am a past president, at its meeting held at St. Paul, in December, 1939, recommended the appointment of a committee for the purpose of preparing legislation affecting this subject to submit to the coming session of the legislature. Because of the fact that the insane person is suffering from a mental disease, it is my opinion that a committee from your

body ought to be appointed to work in conjunction with the committee from the County Attorneys' Association, and to jointly prepare laws and recommendations, to the end that they be incorporated in our statutes, with the hope that they will discourage the defense of insanity in those cases in which insanity does not in fact exist.

In entering upon the subject, I do not know of better words to express your feeling and mine, than the words of Judge Stone of our Supreme Court, in the case of *State ex rel. Sundberg vs. District Court of Hennepin county*, when he said:

"The natural solicitude of any judge for the public safety in these matters is to be commended rather than disapproved. There have been cases where innocent human life has been the penalty for the mistaken release of a person acquitted of crime on the ground of insanity and thereupon committed to a sanitarium. The medical profession, particularly those of its members who have made the study of mental disease a specialty—and outstanding among the latter should be the superintendents of our public hospitals for the care of the insane—are as alive to the danger as we of the legal profession. Whatever our own opinions may be, two compelling facts remain: (1) The patient after he is restored to sanity has a right to liberty, which not even the state can lawfully deny. (2) It is competent for the Legislature to say that the certificate of the superintendent of the institution where he has been under treatment shall be sufficient evidence of the fact entitling him to liberty."

Prior to 1931, a person acquitted of crime on the grounds of insanity and committed to a State Hospital or Asylum for safe keeping and treatment, could not be released except upon order of the Court committing and the written certificate of the Superintendent of the Hospital where he was confined, that the person had recovered and that no one would be endangered by his discharge. Chapter 364 of the Laws of 1931, changed the prior law and provided that upon the certificate of the Superintendent of the Hospital that the person had recovered and that no one would be endangered by his discharge, that then and in that event the person must be released. It did away with the provision of the

*Read before the County Officers' Meeting, Saint Paul, Minnesota, February 24, 1940.

right of the District Court to release. It made it mandatory upon the committing judge to release upon the presentation of the certificate from the Superintendent of the Hospital. In the Sundberg case, a District Judge refused to release the patient on the certificate of the Superintendent, because the Court felt that in justice to society and the protection of the public, that the Court was not at that time satisfied that the patient could be released with safety. In the Sundberg case the Supreme Court held that it was mandatory upon the District Court, under the terms of the 1931 law, to release the patient. You can see that three interests were in conflict. The medical profession stated it to be a fact that the person was cured, the legal profession, as represented by the District Court, felt that the patient could not be released with safety to the public, and third, the laybody of the legislature said: "Yes, we will disregard both the medical and the legal profession, and return the person to society." Here again we have an illustration of the fact that the blame should not be placed at the door of the medical or legal profession, but in the hands of the great majority of the laypeople, who make up the Commonwealth.

It is well settled that a person cannot be legally punished for any act committed by him while insane, although such act would be criminal if done by a sane person. Since a criminal intent is an essential element of crime, if by reason of insanity a person is incapable of forming any intent, he cannot be regarded by the law as guilty. No one, of course, wants to punish an insane person who is really insane. That person is a ward of the State. He should undergo confinement in the interest of public safety, and given such treatment as is necessary for mental illness. On the other hand, people should be discouraged from the trumped up defense of insanity where no insanity exists, and it is to these manufactured defenses that your association and mine should direct its efforts. From my experience as a prosecutor, I have come to the conclusion that there is a mental twist in all persons committing felonies, and if they are encouraged in the belief that upon a defense of insanity, a jury will acquit them and in a few weeks after the acquittal, they can walk out of a State Institution and again return to society and take their places as normal individuals, then and in that event the orderly administration of justice, in the

protection of the public and the public's right, will be hampered and nullified, and those who commit serious crimes, who have sufficient funds, friends and influence, will go free at the expense of the indigent prisoner, who, perhaps, has more of a mental disease than his more fortunate brother in crime.

The legislature of the state of Minnesota makes the laws. Our statutes at the present time read as follows:

"* * * but he shall not be excused from criminal liability, except upon proof that at the time of committing the alleged criminal act, he was laboring under such a defect of reason, from one of said causes, as not to know the nature of his act, or that it was wrong."

In the first instance then, in order to discourage the defense of insanity, I feel that our statutes applying to criminal responsibility of insane persons, should be amended to read as follows:

"Every person is to be presumed sane, until the contrary is proven, and that to establish a defense on the ground of insanity, it must be clearly proved that at the time of the committing of the act, the person was laboring under such a defect of reason, from a disease of the mind, as not to know the nature or quality of the act he was doing; or if he did know it, that he did not know he was doing what was wrong."

I would go a step further and suggest that if the mental competency of the offender was occasioned by himself, with the intent of committing the offense while in that mental condition, then such mental disturbance shall not be a defense.

The legislature should make provision giving the right to District Judges, where insanity is alleged as a defense, to comment upon the weight and value of the evidence, and to caution the jury concerning the defense, and this should be especially true where the judge is convinced that the attempted defense is a built up one.

As you men know, the County Attorney, under the laws of the State of Minnesota, is required to appear for the patient at all insanity hearings. He is attorney for the patient, and is there at the hearing to protect the rights of the patient. From my experience in listening to testimony and the examination by medical men, I have come to the conclusion that the really insane person indicates the mental disease by acts, conversa-

tions, etc., for a considerable period of time, and that in a majority of cases, the disease creeps on and can be detected long before the commitment is issued. I have seen some real insane people in my life. I do not remember one that evidenced any intent to destroy another life, although they have considered taking their own lives, and some of them, after they are released from institutions, have taken this step. The point I am making is that the real insane person, from my experience, is not bent on destruction of others, but that the sane person who is accused of murder, seems to want the public to think that he is insane, because he has taken another life, even when that life is the source of his life. I know that lives are taken without any premeditation. I know that lives are taken in a fit of anger. I know that lives are taken through wilful negligence, but our statutes are such as to distinguish these different takings of human life, and to provide punishment for different circumstances in connection with the taking, and that is why we have the different degrees of murder and manslaughter, and within late years, the statute covering death by negligent operation of a motor vehicle.

Of course, with the development of the criminal law, defenses are developed. We do not want to deprive any man of a legitimate defense, but defense of insanity should be and must be safeguarded.

Our statutes provide that whenever a person is under an indictment or information, and before or during trial, and before a verdict is rendered, shall be found to be insane, etc., the Court shall forthwith commit him to the proper State Hospital or Asylum for safekeeping and treatment, and if he has homicidal tendencies, he shall be committed to the asylum for the dangerous insane. If, after the person has recovered, he is then to be returned and placed on trial under the indictment or information. Another provision of the statute provides that where a jury acquits a defendant on the grounds of insanity, and shall so state in its verdict, then the Court commits to the hospital or asylum, and the person is there kept until recovery, then to be released, if no person is endangered by the discharge. The first provision provides for the insanity hearing before or during trial, and the other provision covers the acquittal on the ground of insanity.

As the law now stands in Minnesota, a person can be acquitted of a crime today, confined in a State Asylum tomorrow, and released the next day. The Courts have nothing to do with the release under the law as it now stands, but your profession has. It is the certificate of one of the members of your profession who returns the defendant to society and who guarantees the public that he is no longer dangerous. What an important part your profession plays in the administration of criminal law. With the law in Minnesota as it is, your profession and mine cannot be blamed by the public for the eventual outcome of these particular cases. It is interesting to know how other lands and other states determine the punishment in cases of this nature. In England, the confinement is to be until his Majesty's pleasure is known, and in Canada, until the pleasure of the Lieutenant Governor is known. In the United States, some states provide that a person acquitted of murder on the ground of insanity, is to be committed to prison until the further order of the Court. Other states provide that the confinement is to be until the prisoner is discharged by the Governor, or by act of the legislature. In another state, a person acquitted of murder or manslaughter, by reason of insanity, is to be committed for and during the term of his natural life, with a provision that he may be discharged by the Governor, by and with the advice and counsel of the hospital and prison authorities.

The state of Michigan, during the regular session of 1939, passed an Act known as Senate Bill No. 93. This Act provides that whenever any person charged with murder, under the laws of the state, and who has been bound over to the court having jurisdiction over such case, the clerk shall immediately notify the State Hospital Commission and such Hospital Commission shall as soon as possible, cause the person to be examined to determine his mental condition and the existence of any mental disease or defect, which would affect his criminal responsibility. The Commission shall designate three psychiatrists for the purpose of making such examination. The report of such psychiatrists then is filed with the Clerk of Court, and becomes accessible to the court, the probation officer, the prosecuting attorney and the attorney for the defendant. The Act provides that after a person is acquitted of the crime of murder by

reason of insanity, he shall be forthwith committed to the State Hospital for the criminally insane for the remainder of his natural life. The Governor may, however, discharge such person upon recommendation of the State Hospital Commission based upon investigation by it.

The new Swiss Criminal Code of December 21, 1937, provides as follows:

"Sec. 2. *Responsibility*. ART. 10. LACK OF RESPONSIBILITY. Whoever because of insanity, idiocy, or grave disturbance of mental competency at the time of commitment of the offense shall be incapable of recognizing the illegality of his act, or whoever by these reasons shall be incapable of acting in accordance with his insight into the legality of his act, shall not be punished.

"ART. 11. PARTIAL RESPONSIBILITY. If the offender, at the time of his act, was mentally disturbed or his mental competency diminished or if he was mentally retarded to the extent that his capacity to recognize the illegality of his act or his capacity to act in accordance with this insight was diminished, the court, in its discretion, may impose a less severe penalty (Art. 66).

"ART. 12. EXCEPTION. The provisions of Art. 10 and 11 shall not be applicable if the serious disturbance or retardation of the mental competency of the offender was occasioned by himself with the intent of committing the offense while in that mental condition.

"ART. 13. MENTAL EXAMINATION. The prosecutor or the court, when in doubt as to the responsibility of the accused, shall order a mental examination of him by one or more experts. A mental examination shall be ordered if the accused is a deaf-mute or if it is alleged that he is an epileptic. The experts shall state the condition of the accused and also give their opinion whether he requires care in a mental hospital and whether his condition is dangerous to public security and order.

"ART. 14. DETENTION OF INCOMPETENTS, ETC. If the incompetent or partially responsible offender is considered so dangerous to public security and order as to necessitate his confinement in a mental hospital, the court shall order his detention. The court shall suspend the execution of the sentence against a convicted person who is partially responsible.

"ART. 15. CARE OF INCOMPETENTS. If the condition of the incompetent or partially responsible offender requires his treatment and care in a mental hospital, the court shall order that treatment and care. The court shall suspend the execution of the sentence against the convicted person who is partially responsible."

After carefully studying the different laws of foreign countries and of the different states of the union, I am proposing that a law be so framed for adoption by the legislature, providing that when any person who is tried for a felony and is acquitted by reason of insanity, that that per-

son shall be committed by the court to a State Hospital, and if the crime is murder or manslaughter, to the State Hospital for the criminal insane, until the further order of the court. I would have the law carry a provision asking the jury to say in their verdict, whether or not in their opinion the defendant had insane delusions, irresistible impulses, emotional insanity, or was generally insane. If the court can comment on the defense of insanity, the jury would have no trouble in making these special findings.

I then would provide that a commission be established consisting of the superintendents of the state hospitals. After the commitment, this commission would review the case of the defendant, and they would certify it back to the committing judge. If their certificate showed that the defendant was cured, then the Court would impose such sentence as deems commensurate with the circumstances surrounding the crime. The situation would then be that there would be punishment imposed if the insanity passes, and if the person is really insane, he, of course, would be continually confined to the State Hospital. The defendant should not object. If he was found guilty and sentenced to a penal institution and then became insane, he, under our law, would be removed from the institution to a state hospital, and sent back again after he regained his mental poise. If the defendant is sent to a state hospital before he is confined, he should pay some penalty for his act, and this should be the intent of the law.

I believe that we should also define a psychiatrist. If the testimony of these medical men is to be taken in criminal trials, they ought to qualify. I would suggest that you ought to consider a law saying that before a physician can qualify as a psychiatrist, for the purposes of giving testimony in a criminal case, that he should have at least five years of practice confined wholly or substantially to the diagnosis, care or treatment of persons suffering from nervous and mental disease, or mental defect. This would apply both to the State and to the defense, and if the law is passed by the legislature, the jury and the court would have the benefit of the testimony of really qualified men.

It is considered unethical for a prosecutor to appear as a defense attorney in the matter of criminal prosecutions in his own state. In my opinion it would appear to me to be unethical

for a medical practitioner, who is employed by the State, to give testimony as a qualified expert for the defense, especially when that doctor occupies the position where he might be called upon to pass on the sanity of the person involved in the action in which he testified. I believe that your association would not oppose the introduction and passage of a law prohibiting such an employee of the State to appear as a defense witness in criminal cases.

There is a presumption in law that insanity continues until the contrary is shown. As the law now stands, the beneficiaries thereof are not convicted criminals, but wards of the State, undergoing treatment in the interest of public

safety. As the law stands, the question of recovery is one for members of your profession and not mine. The release of an insane patient is a legislative act, and is controlled by the statutes of the State.

Our laws ought to be safeguarded and can be safeguarded by the united action of your association in conjunction with the prosecutors of the State, and the general public. It is my hope that by joint action, we will be able to convince the legislature of the righteousness of our stand, and if that body will follow our recommendations, the State of Minnesota will assume an outstanding position in the realm of jurisdiction in discouraging the defense of insanity in criminal cases, in an unjust cause.

EXTENSION OF GROUP HOSPITAL SERVICE*

ARTHUR M. CALVIN

Executive Director, Minnesota Hospital Service Association
Saint Paul, Minnesota

GROUP hospitalization, as we all know, has played an important part in the plan for providing health at a low cost. Group hospitalization plans, which started with the simple idea of group budgeting to solve the problem of unexpected hospitalization, like all new, untried plans, have had their difficulties. Pioneering in any new field is no easy task.

Because of the necessity for sound development, these plans, so successful in urban centers where large employed groups were easily contacted, have been slow to spread throughout the country into the smaller towns and sparsely settled areas where group contacts are difficult.

A few years ago the feasibility of these plans was questioned. Today there is no longer a question of feasibility. Non-profit group hospitalization plans have proved successful—so successful that farmers and residents of small towns are asking for the same worry-free protection for themselves and their families that the city dwellers enjoy.

Hospitals, too, have expressed their desire for this service. They realize that an increase in patients or bed occupancy will mean lower oper-

ating costs, and that hospital administrators will have fewer credit and collection problems. The public is demanding that hospitals provide such a plan.

Medical men, too, more and more, are realizing the value of hospitalization plans not only for their patients but for themselves. Now, a doctor can urge a patient needing hospital care to have it, knowing that the patient's recovery will not be retarded by worry over a big bill, knowing too, that when the hospital bill is paid by the non-profit hospital service association, the doctor receives his fee sooner.

Employers favor the idea because they are no longer asked for loans or "cash advances" to cover unexpected hospitalization. The community, as a whole, which is relieved in large measure of the burden of charity hospital care for the low-income group, should sponsor the plan.

Statewide Plans

Answering these multiple requests for service, several of the approved non-profit hospital service plans are engaging, at the present time, in statewide development. Among these are: The Hospital Service Corporation of Alabama; The

*Read before the County Officers' Meeting, Saint Paul, Minnesota, February 24, 1940.

Plan for Hospital Care of New Haven, Connecticut; the province of New Manitoba Hospital Service Association with headquarters in Winnipeg, Manitoba; the recently established Colorado Hospital Service Association; Group Hospital Service, Inc. of Wilmington, Delaware; Group Hospitalization, Inc. of Washington, D. C.; the Associated Hospital Service of Maine; The Associated Hospital Service of Baltimore, Maryland; the Associated Hospital Service of Massachusetts; Michigan Society for Group Hospitalization; Group Hospital Service, Inc., of St. Louis and Kansas City, Missouri; Hospital Service Plan of New Jersey, headquartered in Newark; Hospital Service Association of North Carolina at Chapel Hill and the Minnesota Hospital Service Association. The Hospital Service Associations of Rhode Island, Iowa, Texas and Wisconsin are also planning state-wide developments.

Brief Recapitulation

Before going into the state-wide picture in detail, I should like to sketch for you, briefly, the growth and accomplishment of some of the large non-profit plans. It is estimated that today, over five million people in the United States are actually entitled to benefits under approved, non-profit hospital service protection. New York leads the field with a total of 1,305,958 persons covered. Minnesota continues to retain second place with a total of approximately 310,000 persons covered. Cleveland ranks third and Philadelphia, under the guidance of Mr. van Steenwyk who did so much for the Minnesota Plan, is rapidly coming to the fore. Rochester, New York, has the highest percentage of participation.

Because we are primarily concerned with Minnesota, you will be interested in hearing how rapid the growth has been here in the past few years. In January of 1936, after operating two and one-half years, Minnesota had 12,037 subscribers, 12,000 dependents; a total of 24,037 persons protected. In January, 1939, a year ago, a total of 245,112 persons. At the end of December of the same year, 309,216. During the six years that the Minnesota Hospital Service Association has been in existence, 68,740 people have been hospitalized for a total of 482,610 hospital days, and a saving to subscribers of \$1,990,249.35. These, I think you will agree, are imposing figures.

Problems in Statewide Development

Minnesota, pioneering along with other states in state-wide development, has been delayed somewhat in her activities for a multitude of reasons. She has, in the first place, had the same general problems that confront other plans, among which are those of educating people in rural communities to make fuller use of their local hospitals. Hospital service, unlike rural electrification or telephone service, is an intangible commodity and intangibles are, of course, more difficult to sell.

Sponsoring of the plan in small communities is a most important question. The hospital itself, of course, should be the central point of interest and enthusiasm, but the plan should have more than hospital sponsoring. It should be endorsed by the medical society, the hospital trustees, civic organizations and persons interested in general in community welfare. These are all important factors which contribute to the successful development of the plan.

Another problem general to most plans is that of the proprietary hospital. Hospital service plans, as we all know, have been developed primarily for the altruistic purpose of helping people to help themselves in securing hospital care when they need it. The hospital service organizations have been reluctant to spread into communities where it might appear that the association was enticing patients away from some hospitals and favoring others. This problem of proprietary hospitals has been largely cleared up in several districts of our state by working in close conjunction with the medical societies throughout the state, and by the actions of the various hospitals themselves in making application for membership in the Association. Proprietary hospitals may join the association here in Minnesota by changing their corporate structure from profit-making to non-profit.

To simplify promotional activities here we have districted the State of Minnesota into Medical Counselor Districts corresponding to the State Medical Society districting. While this may not be an entirely satisfactory method, because all hospitals within a certain district do not apply for membership in the plan at the same time, it seems, at the present time, the most feasible one.

We have, now, nine Medical Counselor Districts and are starting work in those districts in which most hospitals have indicated their desire

to join the plan. As an illustration: Take one city in Minnesota, a city that has been ready and acceptable to the Hospital Service Association for some time. There were, in this area, a number of hospitals not acceptable as member hospitals of the Association because of the fact that they were privately owned and incorporated for profit. Recently we have had meetings in that area with the hospital administrators and medical men of those districts to discuss the problem of proceeding with rural enrollment. At these meetings it was suggested that proprietary hospitals desirous of joining the plan, should reincorporate as non-profit institutions. After such reorganization they were to conform to the regular requirements of all hospitals seeking admission to the plan by: (1) securing the approval of their Boards of Trustees and medical staffs to join the Association; (2) securing the approval of their component or county medical societies and, if possible, sponsorship of the plan by some local civic agency, such as the Chamber of Commerce, Rotary, Kiwanis or other civic body; (3) presenting their formal written application for membership. The last step, of course, is the approval by the Board of Trustees of the Minnesota Hospital Service Association. To aid hospital administrators in disseminating information about the plan, representatives from our Association have given talks before these various bodies.

After discussing various problems affecting our extension work, those present at the meetings agreed that if, by a certain date, all the hospitals that desired to become members of the Association had not met the requirements, the Hospital Service Association was to feel free to go ahead with promotional work in that area.

Foremost among our own particular problems here in Minnesota has been our lack of enabling legislation defining our scope and powers. We hope soon to have such enabling legislation and will appreciate your coöperation in this. Another problem was where first to start and how to proceed.

Proposed Program

The principal reason for the development of non-profit hospital service plans in the rural areas is exactly the same as that which first brought non-profit plans into existence, namely, the desire to make good hospital care available to

more people through a low-cost budget plan. People, in general, are utilizing hospitals to a much greater extent than they did a few years ago as a study of hospital occupancy figures reveals. But this increased utilization is primarily in metropolitan and government hospitals. Rural development, therefore, will be successful in direct proportion to the preliminary educational program.

Promotional Procedures

Once the hospitals in a district are approved for membership, our next step is to prepare the field so that we may contact subscribers. This preparation must be a coöperative venture between the hospital administrator and trustees, community leaders and the Hospital Service Association. This work cannot be done alone by the Hospital Service Association representatives. Meetings should be held with Civic organizations such as the Chamber of Commerce, Rotary, Kiwanis, Lions, etc., to acquaint the local business men with the plan. I cannot stress strongly enough the necessity for adequate newspaper publicity in the smaller communities. Newspapers are, in many instances, the only adequate means of disseminating information in sparsely settled areas and it has been adequately proven to us from the promotional work in the few communities that we have already developed that the most successful results were obtained in the communities where we had most newspaper publicity. In areas where newspaper publicity was difficult to obtain, we have stimulated enthusiasm by the wearing of "Blue Cross" buttons similar to those of the Red Cross. We have urged doctors and community leaders to wear these pins and their coöperation has helped tremendously. Chart talks and our educational film, "When Pennies and Seconds Count" have also stimulated enthusiasm.

I should like to say here for the benefit of those who have been eager for advance publicity about the hospital service plan that we have found it unwise to have a great deal of newspaper publicity until immediately before we are ready to start promotional activities. Publicity too much in advance of our actual entry into the field gives commercial insurance companies an opportunity to capitalize on our efforts.

Once we have entered a community our promotional activities are more or less similar to

those in metropolitan areas. Our representatives contact the heads of business firms to ask for company time to explain the plan, and payroll deductions to facilitate collections. The plan is explained through a chart presentation showing what benefits are derived, the costs to the subscriber, etc. To facilitate the work of the representatives and save time and promotional expense, it is advisable, wherever possible, to have people in small groups in similar industrial endeavors to join the Association in one large single unit. Let me explain this in detail:

In Stillwater, Minnesota, where we have had a most successful development, the Stillwater Association (which corresponds to our Chamber of Commerce), offered to act as group leader for people in small firms, that is, firms where only one or two were employed. The Hospital Service Association sent mimeographed letters to those eligible for this group and held two community meetings. When 40 per cent of the group was secured, subscription payments were made to the Stillwater Association on a quarterly basis. Similarly, instead of taking each small grocery and butcher shop as an individual unit, the Stillwater Grocers' and Butchers' Association volunteered to act as group leader for that organization. Store managers attended an explanatory meeting in a body, took literature and application cards to their individual stores, explained the plan and returned the signed application cards together with quarterly payments to the Butchers' and Grocers' Association secretary and so that group was successfully organized. The city employes of Stillwater joined in a body on a payroll deduction basis. School employes and teachers similarly joined in one unit. All such systems for simplifying our promotional and collection procedures are, naturally, most acceptable to the Association. Similar promotional activities will be encouraged throughout the State.

How About the Farmers?

One of the first questions asked us about state-wide development is "how are we going to enroll the farmers?" Enrollment of farmers does present a problem in that they are scattered over a large area and it is frequently difficult to contact them in group meetings. We do find, however, that farmers can be successfully enrolled through banks, coöperatives, creameries, Farm Bureaus or like organizations. We have already developed

a most satisfactory Farm Bureau Group in Hennepin County, and County Agents, for the most part, throughout the State, are not only helpful but eager to bring this protection to their farm patrons.

The Hennepin County Farm Bureau group was completed after several meetings between our representatives and influential farmers in the Farm Bureau. The farmers themselves were largely instrumental in securing applications after they were thoroughly informed about the plan. Payments are made on a quarterly basis to centrally located farmers who remit to the Secretaries of the Farm Bureau units who in turn remit to the Hospital Service Association. The Hospital Service Association bills only the Farm Bureau Unit Secretary and the Farm Bureau takes care of all further billing and collection. A primary requirement, of course, for Farm Bureau participation, is membership in the Farm Bureau itself.

An ideal enrollment of farmers so far as the Hospital Service Association itself is concerned, would be through creameries where a deduction from cream checks might be possible. However, the Farm Bureau County Agents have been so coöperative and so interested in this development that those groups organized have been very successful.

In Stillwater, we accepted farm groups through the banks. When a certain percentage of the farm patrons of the bank had signed application cards, protection became effective for the bank's farmer patrons.

The State of Missouri has had a most interesting experience in the enrollment of farmers. They started their initial move for farm service some two years ago. Informal discussions of the plan with officials of the Missouri State Farm Bureau led to its adoption as an integral part of the Bureau's service program to farmers.

Realizing the importance of a preliminary educational program at the very outset, the Missouri Hospital Service Association started a program of publicity through the Farm Bureau's weekly newspaper with informative articles published about the hospitalization plan for a period of some eight months. At the same time, hospital service was a principal topic at all county bureau meetings. In Missouri, arrangements were made with the State Farm Bureau to accept membership dues quarterly and to remit one

check for the whole state to Group Hospital Service. Because farm income is seasonal, arrangements must be made consistent with the ability of farmers to pay conveniently. Missouri insisted that every county group be personally addressed by representatives of the hospitalization association before applications were accepted.

Commercial Insurance Companies

We believe heartily in insurance principles, but we are convinced that profit-making corporations cannot begin to give so much for the money as non-profit.

We must stress here the difference between the "service contract" which the non-profit hospital service plans provide and a "cash indemnity" policy which insurance companies offer. Under the "service contract," the hospital is paid directly for services rendered the subscriber or his family. Under a "cash indemnity" policy, all too often the subscriber receives the check and forgets his obligation to his hospital and doctor.

The "Blue Cross" card of our hospital service association not only eliminates the need for a down payment on admission to a hospital but also eliminates the filling out of claim blanks and the correspondence necessary to effect a reimbursement from an insurance company. This is an important difference to the subscriber and a much more important difference to the hospital as it assures the hospital its payment. Yes, you may say, "But why not take an assignment of the insurance claim?" Many of our Twin City hospitals have learned that this does not mean a secured payment as the insurance contract may have excepted that particular hospitalization under some limitation in its policy. When this occurs, the patient always feels that he has done his best and that his obligation is ended.

Payment to the Hospitals

There is another problem which associations have had to face in extending benefits on a state-wide basis, that is, the payment to hospitals outside of the metropolitan area. In Minnesota we have established a per diem rate of payment to hospitals. This applies to hospitals both in metropolitan and country areas and should, we believe, prove satisfactory.

Serving the Rural Area

We have been asked frequently, too, whether we will establish offices throughout the state. As yet, we do not believe such a plan is feasible as we are endeavoring to keep the costs as low as possible. Our plan, at the present time, is to have a district representative servicing that area when that district is sufficiently developed. It may be entirely possible, however, if the plan grows large enough, to have local representatives in addition to district directors.

Hospital Responsibility

The soundness of the hospital service plan in any community is entirely dependent upon that community itself—the participation and coöperation of the medical profession, the hospital trustees and administrators. I recall, that prior to the Service Association's organization in St. Paul there were many discussions between the hospital superintendents, Mr. van Steenwyk and a few members of the medical profession. The relationship in this small group was most cooperative.

We started with the premise that the plan answered a mutual need of the patient, the doctor and the hospital. It was, to us, more than just a way of filling empty hospital beds. It was an opportunity to provide the means by which patients could secure necessary hospital care and thereby use all of the equipment and skill provided by the hospital. This same understanding must be assumed by the hospital administrators, trustees and the medical profession of the rural hospitals throughout the state.

In many states a definite responsibility is entrusted the communities themselves by asking them to assume the actual promotional costs of the plan. For example, the Alton, Illinois, plan is preparing to serve a town of 16,000 and the doctors, civic leaders and hospitals advanced \$2,000 for promotional expense with the understanding that some may be repaid. Here in Minnesota we ask no such stringent guarantee of responsibility. We do ask each member hospital to pay a small membership fee, dependent upon the size of the hospital, as evidence of good faith. The promotional and operating expense in connection with developing neighborhoods is borne by our central office. Here, too, all mechanical procedures are carried out. Oper-

ating expense is charged back on our books to the new community as it develops.

In Massachusetts, an interesting experiment in state-wide development was conducted. I would like to quote from a letter we have recently received from the director of the Massachusetts plan. Speaking of enrollment on Nantucket Island, he says, "We have enrolled nearly half of the Island, primarily through the efforts of a trustee of the Nantucket Hospital. The local bank acts as the Remitting Agent and we permit our Ward Plan to be available to them. . . . In a community of this size, Mrs. Laprade, the hospital trustee, being a registered nurse, knows all about every resident and does not accept any applications from people she regards as poor risks. As a result, our experience is especially good. It is a rare day that we even question a case from this group. The doctors are most coöperative and if we could duplicate this situation through the various summer communities of Massachusetts we should be extremely happy. There has been little or no acquisition cost. Only once has a member of our Enrollment Staff visited the island and this was to enroll the people under the only two payrolls having ten or more employees. We accept additions to the group quarterly and even oftener because we have explicit faith in the way the job has been done."

East and Middle West Plans

Mention of the Ward plan in the letter above, brings up a new feature as far as we in Minnesota are concerned. Hospital operations in the East, as compared to ours in the Middle West, are somewhat dissimilar as far as hospital economics are concerned. This is due largely to the variation in economic groups. The low income groups in the East have the privilege of utilizing the free wards of hospitals without cost or payment of medical fees. As soon as these people pay for their own hospital care they immediately assume their own doctor bill. This fact, and the factor of large numbers of part-time and unemployed people entail great responsibility for the hospitals in providing free care. Consequently, the wealthy people of the East contribute largely to the endowments of hospitals in that area for such free-ward care.

In the Middle West, those of low income selecting the voluntary hospitals for their care

have been accustomed to pay for ward beds and for medical care. There are no free-wards in the Middle West hospitals. Patients requiring free care may be placed in most any type of accommodations and free medical care is determined by the attending doctor himself. And, then again, of course, we have the tax-supported hospitals which care for many of the low income groups with little or no charge.

The rate structures in the East, in many voluntary non-profit plans, range from \$1.50 to \$2.00 a month for families. We feel these rates are too high for participation of the low-income group in Minnesota. In the Middle West our rates are so much more inexpensive that those in low-income groups who prefer independence to charity can readily make use of the plan. We believe that ours is a rate that farmers, too, will not find exorbitant.

In speaking of state-wide development, we usually consider it from the dual viewpoint of "suburban areas" and "rural areas." Actually promotional work and servicing suburban areas is very similar to that of metropolitan centers. The promotional and servicing of rural areas, because of the wide area covered, presents a somewhat different picture. Despite this, however, a voluntary service plan can effectuate as beneficial a service for those in sparsely settled districts as in the more compact areas.

Forty-five hospitals in the Twin Cities, Duluth, Fergus Falls, Stillwater, St. Cloud, Bemidji, Breckenridge, Moorhead, Perham, Little Falls, Red Wing, Faribault, Bertha, Thief River Falls, Winona, New Prague, Hutchinson, Cloquet, Detroit Lakes, Alexandria, Wadena and Crookston are now members of the Minnesota Hospital Service Association. Several others have fulfilled requirements and have been approved for membership and we shall be in those areas very soon.

We feel that the approved hospital service plans throughout the United States are achieving their altruistic aim of better health care for a majority of people. We know that our hospitals and our doctors who are so rich in their heritage of humanitarian service will give still further of that service in coöperating with these plans.

We know, that in addition to helping the doctor with a few of his problems and the hospital with some of its problems, we are helping to relieve the community of part of its burden of

charity care. The wisdom of providing a low-cost plan here in the Middle West is realized when we find that two of our largest tax-supported institutions in the Twin Cities have noted

a decidedly lower occupancy in their hospitals since our plan's inception. Thus our plan is doing what we wanted it to do—help others to help themselves.

A SURVEY OF HEALTH ACTIVITIES AND PROBLEMS AMONG FORMER UNIVERSITY STUDENTS

CARL J. POTTHOFF, M.D., and C. ROBERT PACE, Ph.D.

The General College, University of Minnesota
Minneapolis, Minnesota

FOR several years the General College has been gathering information about the activi-

For several years the General College has been gathering information about the activities, problems, and attitudes characteristic of young adults who formerly had attended various colleges of the University of Minnesota. Approximately 1,400 questionnaires, 52 pages long, were mailed to a cross-section of men and women who had entered the University in 1924-25 and 1928-29. The replies, received from 951 of these former students, constitute the raw material from which the data reported in this article are drawn.

Broadly speaking, the purpose of the investigation was to gather information which would be helpful in planning a more appropriate curriculum in general education—a curriculum which would be adapted not only to the abilities, needs, and interests of students, but which would maintain, also, a realistic awareness of the kinds of activities and problems likely to characterize the students as young adults in their vocational, home and family, personal, and socio-civic relationships. Among the areas of adult living sampled in the questionnaire was that of health. The present article summarizes the health activities, problems, attitudes, and costs reported by these former University students.

Before reporting specific information concerning health, it is necessary to describe these adults briefly in terms of their educational, occupational, economic, and cultural status, so that the data with respect to their health practices may be viewed from a proper perspective. Educationally, a little more than half of these young adults graduated from the University; and about one-third of them spent only two years or less at the University. When the survey was made the group

ranged in age from twenty-three to forty-eight, with the median around thirty. About 70 per cent of them live in Minnesota. Among the older group (those who entered the University in 1924-25) three-fourths are married; and among the younger group (those who entered the University in 1928-29) half are married. Their jobs, for the most part, are good ones. A third of the men are in the professions. A fourth are in semi-professional and managerial jobs, such as accounting, banking, and manufacturing. Another fourth are in skilled trades, clerical work, or retail business—jobs such as retail dealers, bookkeepers, insurance agents. And the remaining small group (about 15 per cent) are found in semi-skilled jobs, minor clerical work, or minor business occupations. These jobs, apparently, provide them with a relatively high standard of living—the median income of the older group being \$2,400 and of the younger \$1,800 per year. In the total group, men and women combined, one-fourth have incomes above \$2,700 and one-fourth have incomes below \$1,300 a year. In comparison with the status of families in general in Minnesota and the Northwest, it may be said that this group of former University students stands in the upper one-fourth in terms of educational, occupational, economic, and cultural advantages. With the general character of the group thus briefly described one may now consider their health practices from a proper frame of reference.

Attitudes and Opinions Related to Health

This group had very little health education at the University. Some of them had a two-credit course in hygiene. Yet some of their attitudes are surprisingly liberal. Ninety-four per cent of them

believe that postmortem examination of human bodies can be justified for medical research, only about 1 per cent disagreeing. The remainder are doubtful. Eighty-six per cent of the men and 84 per cent of the women believe that birth contraceptive information should be available to all, and less than 10 per cent disagree. About 20 per cent of those questioned were Catholics. Attitudes otherwise include the following:

	Per cent of Men Women	
Biology of human reproduction should be taught in high school.....	Agree	84 88
	Disagree	7 3
Insanity is a disgrace that shouldn't be talked about	Agree	4 1
	Disagree	79 90
Feeble-minded persons should be sterilized	Agree	85 88
	Disagree	5 4

Concerning sterilization and many other controversial issues, many pros and cons and practical considerations influence judgments. Nevertheless, the insider frequently must modify his efforts because of the opinions of those who have not so thoroughly investigated a question. These people were given ample opportunity to profess indecision.

	Per cent of Men Women	
Government should adopt stringent requirements for licensing auto drivers	Agree	91 95
	Disagree	3 2
People should know much more than they do about contagious diseases	Agree	96 95
	Disagree	2 3
It is desirable to keep strict quarantine for mumps and chickenpox.....	Agree	74 85
	Disagree	7 6
Expense often keeps people from going to a doctor when they feel they should	Agree	87 94
	Disagree	7 1

Needs in Education

These former students now wish they had received education on various health subjects. The following, in per cent of total persons tested, signify this need:

	Per cent of Men Women	
How to meet nutrition needs for myself and family on the money available	23	33
How to select a medical doctor	38	39
How to select a dentist	34	30
How to prevent colds (!)	64	62
How to care for colds	54	46
What vaccines and serums are effective for various diseases	45	49
The human anatomy.....	29	34
Human physiology	32	33
How to get information concerning heredity	27	36

What the scientific basis is for claims of chiropractors, electric healers, naturopaths, and other practitioners.....	44	35
How to give first aid.....	48	58
What reliable sources of health information are available	41	40
How the government protects against worthless patent medicines.....	29	35
What health standards regulate the milk supply	22	34

Slightly more than one-third of these persons are parents. Answers concerning education needs strongly reflect this fact. Non-parents do not seem interested in questions involving child care; parents are markedly curious.

	Per cent of Men Women	
How to meet emotional problems in children, such as fears, stubbornness, etc.	30	40
What disciplinary measures to use.....	29	38
What diets are desirable for young children	24	28
How to prevent friction, jealousy between children of a family.....	18	25
How to train children in physical habits..	21	23

Efforts Toward Health

Forty-nine per cent of the men and 53 per cent of the women had a complete physical examination during the year preceding. Among those who did not, the following reasons were cited:

	Per cent of Men Women	
Never got around to it.....	25	10
Felt it was unnecessary.....	58	57
Couldn't afford it	9	12

The remainder failed to state a reason. During the preceding year the medical adviser consulted was:

	Per cent of Men Women	
Physician	72	79
Surgeon	18	13
Eye, Ear, Nose, and Throat Specialist..	33	36
Dentist	82	90
Osteopath	5	6
Chiropractor	3	3
Christian Science Practitioner	4	35

About 50 per cent stated that they read regularly articles on health. About 6 per cent had investigated to determine what diseases occurred with more than usual regularity in their families. Other health practices reported were:

	Per cent of Men Women	
Included in budget provision for medical care	15	24
Paid an organization for group medical benefits	18	12
Paid an organization for hospital benefits	25	25

Cost of Medical Care

These people were questioned concerning their medical expenses. The figures obtained are

shown below. They are not set forth as representing actual outlay, but rather as representing what these people said they paid—and perhaps in some instances this may mean what they want others to think they paid. The investigators did not inquire into specific expense items, and no vouchers were shown. All through, this report is intended to show reactions toward health matters. It behooves the reader of survey results to keep this point of attitudes in mind, even if he challenges statements elicited.

Cost of medical, dental, and hospital care the preceding year was stated to be:

	Single	Married, but no children	Married with children	Total group
Median	\$26	\$40	\$100	\$46
Q ₃	61	103	187	119
Q ₁	12	15	38	17
Q	25	44	74	50

The number of persons included in the above estimates of medical costs for the total group are as follows:

1 person.....	37%
2 persons.....	30%
3 persons.....	19%
4 persons.....	10%
5 persons.....	4%

It would be of interest to check back thoroughly on these cases. One might thus find that people who undergo a heavy medical expense in one year continue to give that figure as their annual expense for years after.

When these people were asked whether they were ever in debt for medical care, 28 per cent replied in the affirmative, 70 per cent in the negative. Anent this point, 43 per cent of the men and 30 per cent of the women had bought goods on the installment plan, and about one-third remarked that it is hard to keep out of debt. About 25 per cent desired information on where free medical service could be obtained.

These apparently average ex-university students belonging to higher general economic levels appear to favor "socialized medicine." One question among many shows this tendency, and also shows the increasing tendency in younger people to believe thus. The question was stated rather peculiarly: "Private medical doctors should encourage trends to socialized medicine."

	Older group 1924-25	Younger group 1928-29
Agree	41%	45%
Disagree	29%	23%
Undecided	30%	32%

It should be noted that most of these people were not subjected in school days to vigorous presentation of either side of the issue.

Questions for Health Education

Many people object to surveys and some doctors will question the findings of this survey. It is presented simply as a widely published survey, prepared by educators in conjunction with Doctors Shepard and Dukelow. It represents a sincere attempt to get, as an ultimate objective, better health education. One general question posed is, "What need in health education is now felt by the post-college adult?"

Educators want to know what to teach about health and disease. How far shall we go in education concerning symptoms and treatment? What special methods does health education require? What perspective views shall be given? Students, prospective teachers, and instructors of prospective teachers seldom hear these questions discussed by those who have stood at the bedside or listened and examined at the office in the rôle of physician. Particularly in the teachers' colleges and other state colleges is the physician-teacher absent. But the reason does not, we think, lie in discrimination against the physician-teacher.

BIRTH RATE STATISTICS

According to a recent statement of the Census Bureau, there were 2,262,726 births in the country last year, a rate of 17.4 births per each 1,000 estimated population. In 1938 the rate was 17.6 and in 1937 it was 17. Low rates were reported for New Jersey—13, Connecticut—13.5, Massachusetts—13.6 and New York 14.4. Arizona had a rate of 26, Mississippi 25.6 and Utah 25.1, while New Mexico led with a rate of 33.7. The figure for Minnesota was 18.9, identical with that for 1938.

EYE DEFECTS CAUSING LOSS OF VISION

WALTER H. FINK, M.D.

Minneapolis, Minnesota

THE trend of modern medicine has a distinct leaning toward conservation; this is especially so in the field of ophthalmology. Conservation as applied to the eye embraces all efforts to obtain and retain whatever degree of sight is possessed in the normal eyes as well as defective eyes. It involves the study of conditions under which the healthy eye may function and still remain healthy quite as much as of the conditions under which the individuals handicapped by abnormal vision may obtain the best visual efficiency. Conservation in this field is of special importance, because the eyes are neglected and abused more than any other organ in the body and are more often permitted to go without treatment or help of any kind. The function of sight is the most important special sense inherited by man, and unfortunately most of us take our eyesight for granted and never think of it as the greatest of our personal treasures which should be guarded constantly.

To more fully appreciate the necessity for conservation measures as applied to the eyes, it is necessary to be acquainted with the results of ocular neglect. That we have not attained a high efficiency in this respect is evidenced by the following:

The last survey of the American Foundation of the Blind states that in 1930 there were 114,000 blind in the United States, or 0.9 per 1,000 inhabitants. It has been conservatively estimated that 72 per cent of all cases of blindness are preventable, and that, with advancing knowledge and increasing care, practically all blindness may be prevented.

To be informed as to the type of eye conditions which fall into the above group, we should review the statistics of any institution for the blind. For example the following causes of blindness were found in cases admitted to the Minnesota School for the Blind during the period from 1925-26 inclusive.

	Per cent
1. Congenital and hereditary.....	38
2. Interstitial keratitis and other luetic causes.....	22
3. Injuries	10
4. Ophthalmia neonatorum	8

5. Trachoma	56
6. Refractive errors	8.78
7. Infectious diseases (measles, etc.)	6.80
8. Other causes—unclassified	4.82

We have here a great field of human service. It should be kept in mind that these statistics apply to but one phase of the subject and our problem has a much wider scope. We should not only consider the so-called important ocular conditions but also the seemingly commonplace conditions of the eye. The problem should therefore be viewed as a whole and the various ocular conditions in all periods of life considered. These periods include the care of the prospective mother, the child at birth, infancy, childhood, the school years, and the adult period extending to the later years of life.

Starting in a chronological sequence, let us consider some of the causes of visual loss. Many ocular tragedies can be prevented if before the birth of the child proper treatment is instituted. In a large percentage of cases, treatment of the mother protects the child against diseases such as syphilis. These prenatal afflictions of the child's eyes in many cases can be avoided if the obstetrician will take the necessary precautions. Likewise, during the birth of the child, ocular damage may occur due to prolonged labor or the use of forceps. Immediately after birth the baby should be examined for congenital defects. Early care may greatly modify the outcome.

Hereditary conditions are not uncommon and every ophthalmologist has had experience in dealing with them. In 1,024 families in which hereditary blindness prevailed, Loeb found that 60 per cent of the 4,155 children produced had inherited eye defects. Hereditary defects other than those of refraction may be present, such as undeveloped pupil or choroid, glaucoma and displaced lens. These are difficult to cope with, but demand early attention. The most common and important defect from our standpoint is congenital cataract.

Many babies become blind because of ophthalmia neonatorum. A generation ago, ophthalmia neonatorum caused more than one-fifth of the

cases of blindness in children. As a result of organized effort, recent admissions to institutions show only one in twenty, or one in fifty, blind from ophthalmia neonatorum, whereas formerly one child in five, or even one in three, was blind from this cause.

Trachoma, an infectious disease of the conjunctiva, is still an active agent in producing poor vision and in destroying sight. It is still the chief cause of blindness in some countries. We are fortunate in this country in having it controlled by the immigration laws which prohibit anyone with trachoma from entering the United States.

Focal infections, syphilis and tuberculosis hold a prominent place as the most prolific sources of blindness. Focal infection is a major cause of eye diseases. In such cases a localized area of disease occurring in remote parts of the body gives rise to iritis, choroiditis, or retinitis, which may terminate in blindness. Tuberculosis may involve any part of the eye, and is a prevalent disease frequently encountered in seemingly healthy young adults. Syphilis is the activator in many ocular tragedies and may destroy sight by its action on the blood vessels of the eye, causing such conditions as interstitial keratitis or choroiditis. It may act also by direct effect upon the nervous system as occurs in locomotor ataxia or general paralysis.

Detachment of the retina, which is usually a sudden separation of the retina from its choroid base, may follow an accident or develop in a seemingly healthy eye, although it occurs much more often in an eye which is myopic.

Glaucoma is the attributed cause of one-seventh of adult blindness among the afflicted persons recorded in our last census.

Old age brings changes which frequently lead to loss of vision. If the crystalline lens becomes opaque as a result of age, it is referred to as a cataract. Cataracts can be removed in an otherwise healthy individual with perfect results, restoring vision. There are no drugs, treatments or devices which alter the progress of a senile cataract.

Of late there has been much in medical literature of the danger to eyes from cosmetics. In certain cases that are sensitive, the dye coming in contact with the eyes sets up an inflammation of the conjunctiva and cornea. If its use is not promptly discontinued visual impairment may en-

sue. Other patent preparations may be harmful. An example is thallium, which is used for the removal of hair from exposed parts of the body. Being absorbed, it may affect the optic nerve and cause blindness.

Our modern life has greatly complicated the accident problem and every oculist can enumerate case after case of accidents to the eye which could have been avoided. Although the eyes are protected by the overhanging bony orbital ridges, by eyelids and eyelashes, many are injured. The largest number of industrial accidents are caused by flying particles such as emery, iron specks, steel chips, pieces of copper, splinters of wood, cinders, glass or brass. These frequently lodge in the cornea and if they become infected, or if they are unskillfully removed, a corneal ulcer may develop with secondary loss of vision. If a foreign body inside of the eyeball is not removed, there is grave risk of losing the eye. We should keep in mind the possible danger of sympathetic ophthalmia in perforations of the ciliary body.

Another type of ocular defect which causes loss of visual efficiency is refractive error. These errors are commonly referred to as hyperopia or farsightedness, myopia or nearsightedness, and astigmatism. It is most important that refractive defects should be recognized early before faulty habits become established. The first six years of a child's life coincide with a significant period of eye growth and with the development of important visual powers. If this development is to proceed normally, children must be unhampered by visual defects.

The care of children's eyes is, therefore, of special significance in the prevention of visual defects, because, lacking mature development, they are very vulnerable to fatigue, and improper care leaves changes of much more serious importance than found later in life. To emphasize more fully the dangers confronting the child's eyes, let us study the following statistics. A recent survey in the public schools of Pennsylvania, which included a group of 200,000 children in kindergarten through the twelfth grade, revealed that 20 per cent of the children were suffering from defective vision or eye strain. These findings conform with conclusions arrived at by other investigations. Reliable authority states that there are five million children attending the elementary schools in the United States

who have eye defects. Other estimates state that approximately two million of the school children are retarded in their studies because of their eyes, and the cost to the public school system throughout the land by this neglect is around 130 million annually. Records reveal that up to a few years ago, even simple eyesight tests were given to less than 17 per cent of the children enrolled. At the present time this percentage is still very low, especially in the rural areas where practically nothing is being done concerning visual checks. Conservation of vision is also an important health problem in college students. During this educational period, many young people discover that all is not well with the visual organs, and poor vision and other signs of eye strain often appear for the first time. In a recent report of the Eye Health Committee of the Student Health Association, it is stated that of 1,250,000 colleges students in the United States, an estimated 15 to 25 per cent enter college with more or less serious ocular defects and many more develop during the college years. These statistics are impressive and drive home the magnitude and the importance of the problem of conserving vision in our young people.

The important thought to remember is that the eye of youth is a growing eye. Like the mind and body it is not mature and its health must be safeguarded. We cannot expect an immature eye to perform the work of a mature eye, or to work under handicaps, without its mechanism being impaired. This point is repeatedly brought home to the oculist who is confronted with these problems in his daily work. Eyes which are performing duties far in excess of their strength, and eyes which are working under a severe handicap, will suffer irreparable damage unless conservation measures are adopted.

Of refractive errors the most difficult to contend with is myopia. In this condition there is usually a hereditary factor as the basis. It is particularly important during school life, because this is the time that it usually develops and increases most rapidly. Rapidly progressive myopia must be considered as an individual problem. The most skilled care is required and mass treatment will not suffice. Every parent must be taught that long delay is dangerous, poor care costly, and coöperation essential, for, if proper measures are not taken, nothing can be done to control the progress of the disease.

Contrasted with the myopic eye is the hyperopic eye. Youngsters with such eyes usually read normally when tested, and a common error concerning the hyperopic eye is that, if the child can see clearly, his eyes are considered normal and are fit for school work without glasses. It is important to remember that farsightedness, unless of unusually high degree, allows clear vision at near and distance.

In children, eye strain is insidious; that is, children in the majority of cases may not be conscious of any eye trouble. Headache or eye fatigue is seldom complained of. Eye strain may be discovered by a combination of some of the following symptoms or signs: red eyes, watery eyes, cross-eyes, squinting or scowling, awkward tilting or twisting of the head, holding the book close to the eyes, sensitiveness to light, nervousness, inattention, lack of concentration, and subnormal sharpness of vision. This latter sign is the best guide, but usually this requires testing, such as is given by the oculist. Many times children so affected are considered backward. These youngsters become discouraged and frequently their personalities become warped. Uncorrected hyperopia, with or without astigmatism, is often the origin of distaste for reading and other school work. The healthy child does not like to be punished by eye strain, and without thinking much about what his sensations are, he avoids instinctively those sensations which are unpleasant. This may cause his entire education to be a failure, but it does save his eyes and nervous system from harm.

When everything has been done to relieve and correct all defects, there remains a small percentage of children, approximately one out of every five hundred, whose eyesight, even with the aid of glasses, is so impaired as to make it impossible for them to carry out the routine work of the school. In the United States we have about 44,000 of these little ones. When a child is found to have uncorrectable, defective vision of such a degree that he cannot see the usual type of the textbook, he should be admitted to a sight-saving class. The first sight-saving class was established in Boston in April, 1913, and at the close of 1935 we had about 1,000 such classes throughout the United States. Continued effort should be made for additional classes, for at least 5,000 are necessary, if a satisfactory educational program is to be pro-

vided for children with serious eye defects. If the defect is so great that a child cannot even see special work, then he must be taught in a private or state school for the blind.

There are a few points pertaining to glasses which seem sufficiently important to mention. The question is frequently asked, "Are glasses always prescribed when the child is examined by an oculist?" Decidedly, no. Many times the symptoms which suggest eye strain may be due to some other condition but an eye examination very definitely eliminates the possibility of a defective eye. Glasses are but one portion of the oculist's work; he examines the eyes from the medical aspect and looks upon them as part of the body. In his various procedures, the question of glasses is but one phase of his examination. With his medical background, he is in a position to analyze the symptoms and findings, and in a good percentage of the patients he finds that the problem is not glasses but some other physical derangement. He considers glasses the same as a crutch and prescribes them only when such special assistance is required. In the case of children, a good percentage of the eye trouble may originate from improper use. In many instances the weakness of the eye is due to head congestion or some other temporary physical upset. Even though the eyes may be slightly far-sighted with a small amount of astigmatism, the oculist knows from experience that such eyes do not require glasses and that under proper care the irritating symptoms disappear. In certain cases glasses may be prescribed as a temporary measure so that the eyes may receive the necessary relief during the very important development period.

The question of how frequently the eyes should be examined is many times asked. Eventually children will have their eyes checked at birth and following this at least yearly, the same as they now do their teeth. It seems far more essential to care for the eyes than the teeth, but usually it is found that emphasis is placed on the teeth rather than the eyes. By periodic checking, an eye defect may be discovered at a very early period and thus more ocular damage prevented.

Some parents do not approve of glasses for their children. If the child needs the glasses it may be an unpleasant necessity, but the fact that one dislikes to see a child with glasses does not

make it any less a necessity or any easier for the defective eyes to do school work without the glasses. For parents to object to an examination of the eyes of their child because they are afraid of the need of glasses, is to follow the example of the ostrich. To choose ignorance can never be considered a good defense against a danger. Periodic examination of the eyes of children is, therefore, worth while. It discloses all the defects and all the degrees of poor vision from which the human eyes suffer.

Another conservation opportunity deserves special mention, namely, children with strabismus (cross-eye). They constitute the largest single group in which there exists serious impairment of the vision in one eye. It is necessary to emphasize three well established facts: that treatment should be instituted the moment the strabismus is recognized even though the child is less than one year of age; that in a high percentage of children, crossed eyes can be straightened by means of proper and complete correction of refractive errors and with orthoptic training; and, most important, that the neglected cross-eyed child loses vision in the deviating eye unless measures are taken to correct the defect before the pre-school age. Vision once lost is rarely regained after the age of six. Almost daily, one is impressed with the fact that physicians, whose advice is first sought by parents of children with crossed eyes, do not properly appreciate the fact that this loss of vision occurs in the deviating eye and is avoidable. Amblyopia, or loss of vision in the deviating eye, results from involuntary suppression or inhibition of vision to prevent diplopia. If treatment can be begun at an early age, this amblyopia can usually be prevented, or vision can be reclaimed by proper treatment.

It is remarkable how many parents bring their children for examination on account of strabismus only when they attain school age, or for esthetic reasons. In some manner they too frequently gain the impression that treatment is unnecessary and without prospect of benefit until the child is ready for school. When informed that the deviating eye has defective vision, they express great surprise and, not infrequently, resentment against earlier advice they have obtained.

In the case of strabismus, preventive measures are of greatest value. It is a fallacy to believe

that cross-eyedness is outgrown. Instead, the earliest attention possible should be given. During the early years of life the glasses relieve the strain and in many cases the eyes adjust themselves. It seems advisable to re-emphasize that in these early years prompt attention should be given and careful supervision carried out because the turned eye does not develop normal vision. Later on when the child reaches school age, fusion exercises can be given to create the desire in the brain for the eyes to work together. Operations should be performed in most cases after the strabismus has become established, because treatment and glasses alone are not usually sufficient. The earlier the child is treated, the less likely is surgery necessary.

Even though the turned eye may be straightened by surgery the vision in this eye is poor and the child continues to use but one eye in seeing. This unilateral amblyopia or partial blindness is far more serious than it has actually been regarded. With the pursuit of various forms of strenuous athletic sports during boyhood, youth, and young manhood, the possibility of injury to the useful eye is a real hazard. The danger may be less during active adult life, unless the individual engages in some industrial pursuit, but it is ever present. It so frequently happens that when in adult life an injury or visually crippling disease occurs to an individual with one amblyopic eye, it is usually the better seeing eye that is the victim. It seems unfortunate that the amblyopia problem exists when we have it in our power to almost entirely eradicate it.

Another point of importance is the avoidance of ocular fatigue in a child. The child's eyes should not be used at close range to any extent compared with the adult. Prior to school days, the eyes looked when they pleased and at what they pleased, and for as long or as short time as they wished. Now they are put to work, and must keep at one job until it is finished, even if they are tired. The result is that much harm can be done not only to the young eyes but to the nervous system as well. We should therefore eliminate many sources of excessive eye strain such as the movies, prolonged drawing, etc., because they cause a high degree of fatigue.

Another important consideration in the prevention of eye defects is proper illumination and the elimination of glare. This problem be-

gins at the very earliest time in life. The problem of light in the school room is of vital importance and the schools as a whole are well and properly illuminated. Home conditions, however, need more supervision. Improper lighting is one of the most important factors responsible for industrial accidents today and the eye hazards of industrial occupation constitute one of the most serious causes of blindness. Fifteen per cent of all accidents are traced directly to poor lighting. Not only could the number of such accidents be materially reduced, but thousands of cases of seriously defective vision could be prevented.

What sort of examination should be made of the eyes? The best is none too good. A good examination will show more completely the exact nature of the disease or defect that is preventing good vision. The examination should be made by an oculist. He has at his command every aid that science affords, and the administration of a cycloplegic is optional with him. Cycloplegia is harmless, and a definite necessity in many instances because in no other way can certain conditions of the eye be uncovered and properly corrected. Cycloplegia enables the physician to measure the true refractive defect of the eye and it also allows him to view the interior of the eye in a thorough way. It is just as impossible to obtain an accurate view of the interior of the eye through a small pupil as it is to see the complete contents of a room through a keyhole. Our best authorities agree that an accurate examination through the normal pupil is impossible because the light from the ophthalmoscope causes the pupil to contract and obscures the complete view. This complete check of the interior of the eye is vital in order to eliminate the presence of early cataract, vessel and nerve diseases of the interior of the eye. We have in the eye a sample spot in the human body, which reveals what is often happening in other parts of the body. Organic weaknesses which affect the heart, kidneys, liver and other vital organs, often leave certain tell-tale signs in the interior of the eye. We should, there, remember that the eye is not an isolated organ, but frequently suffers from diseases of organs far removed, and an eye examination frequently reveals serious disturbances long before they make themselves manifest to either the patient or his attending medical advisor.

Despite all our efforts of prevention there still remains an appallingly large number of individuals who should not have become blind if all the factors tending toward blindness had been combated or eliminated. Fortunately, we live in a progressive age and when a need of this nature exists active measures are taken to obtain results. The National Society for the prevention of blindness, a voluntary organization founded in 1915, has made great progress in the field of visual conservation. It applies the facts advanced by physicians to alleviate the condition of the blind and prevent visual loss. It should be given much credit for the progress in saving vision. The medical men are becoming increasingly more aware of their tremendous responsibility in conserving vision and are taking active steps to combat the factors causing it. To the nursing profession much credit is due for its splendid efforts. The success of the program in the future to a great measure depends upon the nurse, because through her we have avenues of approach which are closed to the oculist.

There still exist certain angles which need further effort and if given proper attention will aid materially in reducing visual loss. One of the most important of these is acquainting the public with facts pertaining to visual matters. The layman should be thoroughly informed concerning the importance of early and regular care of the eyes. This applies to all phases of eye work and especially in the care of children's eyes. Lack of knowledge is the basic cause for ocular neglect. It is within our power to dispel much of this if we will use all the methods at our disposal such as the radio, parent-teacher associations, newspapers, and, most important, word of mouth. More lay groups should be organized, patterned after and working in conjunction with the National Society. If our women organize study clubs to study civic matters, why can't we divert their enthusiasm along this line? To a

great degree it is a question of directing effort in this direction and arousing an interest.

Another phase which is important to mention in this respect is a better fundamental training in eye work for the undergraduate physician and nurse. In many hospitals eye cases are a rarity and consequently the student assumes that ocular matters are of secondary importance. This thought is strengthened and confirmed by the brief course of instruction. The result is that they have very little knowledge or interest in eye cases, and naturally conservation of vision is a foreign subject to them. Let us revise our teaching program, and emphasize the eye more strongly.

In the routine care of patients we should be ever mindful of symptoms which may suggest eye defects because sometimes the eye gives the first clue to general disease. When the opportunity arises teach the parents to watch for eye symptoms in children, especially symptoms of strain or poor ocular coordination.

In conclusion: Prevention of visual impairment is not exclusively a problem confined to the oculist. It affects every branch of medicine. There is lately a growing appreciation for the value of sight and an increasing realization our eyes are not isolated organs, but are subject to many changes secondary to general health and disease. It must be remembered that the eyes are among man's best possessions, and deserve adequate care. Upon no other organ in the human body hangs quite so delicately the thread of happiness as upon the eyes, yet no organ is more active or restless. From early infancy to death, through all awakening hours they function ceaselessly. Considering that 90 per cent of our vast knowledge of the eye has developed in the past fifty years, there is much to be hoped for in the prevention of blindness and saving of sight, provided the individual does his part.

DEATH RATE STATISTICS

According to the latest report of the Census Bureau, the rate of 48 deaths under one year of age per 1,000 live births in 1939, was the lowest rate in the nation's history. In 1938 the rate was 51 and the figure has been decreasing steadily in recent years. Minneapolis' figure of 35.4 for 1938 was the lowest in the country and the figure of 38.8 for 1939 was among the lowest and well below the average.

PRENATAL CARE AND ITS RELATION TO THE LATE TOXEMIAS*

ALBERT G. SCHULZE, M.D.

Saint Paul, Minnesota

AS suggested in the title of this paper, this presentation will not discuss prenatal care in its entirety but will be confined to the late toxemias only, especially those of the eclamptic type.

In recent years much emphasis has been placed on prenatal care as the means of affording the pregnant woman a greater chance of an uncomplicated pregnancy, a greater chance of having a full term living child and greater assurance of the restoration of her former good health. That such might be the case, pre-supposes, of course, that her prenatal care has been adequate and there are several important factors determining the adequacy of prenatal care.

Somebody has defined prenatal care as complete medical supervision of the pregnant woman; preventive rather than restorative. Any measure adopted to combat existing toxemia will prevent further extension of the disease.

That the pregnant woman may reap all the advantages of prenatal care, she must seek medical care and advice as soon as she is aware of her condition and then be faithful in keeping her subsequent appointments.

One visit to her physician in the earlier months of her pregnancy and after that no further consultations, or a first visit in the last trimester of her pregnancy, or when headache, edema, or other signs of toxemia present themselves, does not constitute adequate prenatal care. No patient need apologize for seeking advice as early as her second missed menstrual period.

The Children's Bureau of the Department of Labor recommends that the first visit to the clinic or physician be made at or before the fifth calendar month. This might create in the mind of the patient the idea that it is safe to wait until the fifth month. Many things may happen to a pregnant woman in the first five months of an unsupervised pregnancy.

Visits should be made every month for the first seven months and then every two weeks or oftener if any important or suggestive symptoms arise.

Thomas and Clahr⁵ reporting from the Morristown City Hospital of New York, which is a municipal institution, state that, "despite the gratuitous nature of this service, not one patient applied for prenatal care before the sixth month of gestation," and, "many patients are of the opinion that registration at the prenatal clinic was a necessary preliminary to future hospitalization. Some of these late comers were even aware of having had toxemia in a previous pregnancy."

In Adair's¹ report he states, "Adequate prenatal care was received by twelve per cent of the women whose deaths could be traced directly to toxemia of pregnancy."

In a review of 515 maternal deaths from late pregnancy toxemia in North Carolina, from 1932 to 1936, Bradford² of Duke Medical School found that only twelve patients had received adequate prenatal care (2.3 per cent): 252 were seen for the first time late in their pregnancy either in convulsions or with advanced toxemia; seventy received their first medical attention when in labor; seventy-three saw a physician for the first time after delivery; and in 108 cases there was inadequate prenatal care. Bradford states without any hesitation that one of the most important contributing factors to this high mortality is just plain every-day neglect.

de Snoo of Utrecht, Holland, is quoted as reporting, "over a ten-year period in his clinic, 20,000 deliveries with twenty-seven puerperal deaths, but not a single death was due to eclampsia, and when eclampsia did develop it was due to lack of coöperation on the part of the patient." Danforth⁴ says, "Eclampsia may be reduced so efficiently by painstaking care of pregnant women that we for years past have not had enough cases of this disease to teach internes and nurses to care for them."

These experiences serve to emphasize two facts. The first one is that public education has still much to do and the second one is that good prenatal care can and does accomplish much.

Another factor that contributes to the adequacy of prenatal care is that it must be complete. As far as the late toxemias are con-

*Presented before the Ramsey County Medical Society, Saint Paul, Minnesota, December 18, 1939.

cerned, the patient must be interrogated about headache, nausea and vomiting, the presence of edema and the condition of her bowels. Her blood pressure and her weight must be taken and recorded at each visit and a specimen of urine, preferably of the twenty-four hour excretion, must be examined.

Prenatal care to be adequate must also be intelligent. Steps must be taken to combat unfavorable signs and symptoms. The causes of headache, edema, excessive or sudden gain in weight must be ascertained, and efforts put forth to combat them, and a gradually rising blood pressure must be regarded with suspicion.

Dieckman speaks of prenatal care as having been adequate in some cases but not intelligent. Any prenatal care that is not at the same time intelligent falls short of being adequate. He expresses popular opinion when he states, "prenatal care will not prevent non-convulsive toxemia of pregnancy, but it will, if the various abnormal symptoms and signs are intelligently interpreted, prevent the occurrence of eclampsia and severe pre-eclampsia."

We have not mentioned the symptoms of blurring of vision or epigastric pain because we feel that when these two symptoms make their appearance, the toxemia has advanced to a serious stage and that the patient is on the verge of eclampsia. In this presentation we are concerned rather in a discussion of the prevention of these severe symptoms.

In an attempt to carry out this prenatal program of preventive medicine, there are at least six special symptoms which call for consideration, namely headaches, nausea and vomiting, edema, albumen, mounting blood pressure, and excessive gain in weight. These are not all of equal significance; some are very important and others have only a relative value but the multiplicity and the severity and persistence of the symptoms indicate the seriousness of the toxemia. There is nothing characteristic or diagnostic about the headache of early toxemia. A headache may be due to eye strain, poor sleep, hunger, sinus infection, or poor elimination, and many other reasons, but headaches which are unusual and persistent and tend to become worse must be regarded with suspicion, especially when associated with any of the other symptoms.

Nausea and vomiting in the earlier months of pregnancy are almost a universal symptom of

pregnancy, but when nausea and vomiting return after an absence of several months they are of an entirely different significance and may be a symptom of toxemia although many other conditions, which are rather negligible factors, may cause nausea and vomiting.

The same may be said about edema of the ankles. Many factors may produce it such as pressure of the pregnant uterus, varicose veins, and even an old injury such as a fracture. This type of edema will disappear rather rapidly when the patient goes to bed for a day or so and is often about all gone when the patient arises in the morning.

The remaining three symptoms of albumen, blood pressure, and weight are the most important and a greater significance must be attached to them. The presence of albumen in the patient's urine does not call for much comment; it is either present or it is not present. If present in any marked quantity as determined by ordinary test, a quantitative determination should be made of a twenty-four hour output of urine to note if it is on the increase or not. Williams states that any patient is in serious condition who has albumen present to the extent of one gram per litre.

There is a right and a wrong way to take the patient's blood pressure. It should be taken only after the patient is at physical and mental rest and before a physical or bimanual examination has been made. Many patients amuse themselves by keeping an inquisitive eye on the bobbing column of mercury in the blood pressure instrument. Of course no reading is accurate under such or similar conditions. The blood pressure reading taken at the patient's first visit is important, as it marks the patient's condition at the outset, but it is often a higher reading than her normal because of an uncontrolled mental alertness due to the experiences of a first visit to her doctor. Several readings should be taken before one should feel satisfied as to the correct reading, since a first reading may be ten or more points higher than subsequent ones. Two or three readings at the same point may be regarded as the correct one.

It is well to remember that fatal cases of eclampsia have occurred when the patient's blood pressure never rose above the normal. These are the fulminating types and doctors are rather helpless in the presence of such a condition. The

blood pressure that shows a tendency to gradually creep to a higher level, although never being unusually high at any time, is a pressure that must be regarded with suspicion. Any blood pressure that reaches a systolic of 150 or a diastolic of 100 can no longer be regarded as that of a normal pregnancy, and Lynch showed many years ago, in a large group of closely observed pregnant women in his clinic, that a disturbance in blood pressure took place before albumen appeared in the patient's urine.

There is no doubt but that at the present time the gain in weight of the pregnant woman from month to month is receiving fully as much consideration as her urine and her blood pressure. Any excessive gain which cannot be explained on any other basis is regarded as an occult edema which has not reached the stage of clinical edema and Cummings³ states, "a rapid or excessive gain in weight in the eighth and ninth months were the results of fluid retention and appeared several weeks before definite edema or albumen could be demonstrated."

The patient often asks how much gain in weight is to be expected or is normal. Cummings, in his study of 1,000 patients, has found the gain in weight to be none to one, one, four, four, five, five, three and three pounds respectively in each of the nine months of pregnancy, or a total of twenty-four pounds. None of this weight was gained in the first trimester, and all in the second and third, which, when reduced to a practical every day workable basis, means an average of one pound gain per week in the second and third trimesters. This applies equally to primiparous and multiparous women.

Weldon of Mobile is quoted by Cummings as having adopted a standard of twenty-five pounds as normal gain, and Danforth is of the opinion that weight should be restricted to twenty-five pounds at the most. In Cummings' series of 1,000 cases, 237 had albumen and all of these had gained over thirty pounds in weight. Another observation was that women gaining more than thirty pounds had 50 per cent more signs of toxemia than those gaining twenty-four pounds or less. Babies of ten pounds or more were often born to mothers who had gained on an average of thirty-three pounds. Danforth denies that the weight of the mother has anything to do with the weight of the child, but women who gain excessively are more likely to become toxic.

In order to determine for ourselves the merits and advantages of prenatal care, and to ascertain if the pregnant woman who has adequate prenatal care fares better than her pregnant sister who has had no prenatal care, we have studied the charts of all the obstetrical patients admitted to the Ancker Hospital in a five-year period, 1933-1937 inclusive, and in whom the diagnosis had been made of "toxemia of pregnancy, with or without convulsions."

In all there were 219 such patients. However, in forty-one of them we thought we failed to find sufficient evidence recorded on the clinical chart to warrant this diagnosis and these charts were discarded, leaving a remainder of 178 cases for study. However, to exclude these forty-one cases may have been an error because every patient of this group sent into the hospital from the prenatal clinic exhibited some sign or symptom of toxemia such as headache or edema or elevated blood pressure or sudden gain in weight, and one is not in a position to deny that hospitalization prevented further development of these symptoms.

Of the remaining 178 there were fifty-six patients in this group (31.5 per cent), who had no prenatal care at all. There were 102 (57 per cent), who had four months or less of prenatal care and only twenty (11 per cent), who had more than four months. About 89 per cent of these women had either no prenatal care at all or four months or less.

Of the total number of 178 cases of toxemia found in the prenatal clinic, seventy-seven patients were hospitalized because of the presence or increase in severity of the symptoms. In thirty-one of these, labor took place spontaneously, although the patient was not in labor at the time of her admission to the hospital; in twenty, labor was induced for sufficient reasons and by various methods while twenty-six improved sufficiently to be allowed to go home again. Of this last group, twenty-one returned later on and delivered spontaneously; in three labor was induced, one delivered elsewhere and one died of eclampsia undelivered.

Thirteen patients developed the convulsive type of toxemia. Of this number, eight had had no prenatal care at all, while the remaining five had had some prenatal care, although only one and two months. Of the fifty-six patients who had had no prenatal care at all, eight, or one in

seven, developed convulsions; while in the 122 who had had prenatal care, five, or only one in twenty-four, developed the convulsive type of toxemia. In other words, convulsions developed three and one-half times as frequently in those women who had had no prenatal care as in those who had this type of supervision.

There were twenty-eight fetal deaths in this series or 4.4 per 1,000 of live births. The various causes of death were largely what might be expected and were due to pathology so frequently associated with the late toxemia. In six cases premature separation of the placenta is recorded as having taken place; in one case the cord prolapsed; there were two cases of fetal anomalies while autopsy revealed macerated fetus seven times, prematurity ten times, and cerebral hemorrhage twice. In twelve instances the mother had had no prenatal care and in no instance did she have over three months.

This shows the disastrous effects that lack of prenatal care has on the life of the baby in utero.

The essential features associated with the five maternal deaths are as follows:

Case 1.—One and one-half months prenatal care—hospitalized with 4 plus albumen—delivered spontaneously—premature living frank breech—chill two weeks post-partum—died four weeks post-partum. Cause of death: Chronic suppurative salpingitis, tubo-ovarian abscess, peritonitis and colon bacillus was isolated.

Case 2.—One month prenatal care—hospitalized—induced with bag and vaginal packing—delivered in breech a macerated stillbirth—died on 9th post-partum day. Cause of death: Toxemia of pregnancy. Pulmonary embolus. Acute endometritis.

Case 3.—No prenatal care—hospitalized with convulsions—no improvement under conservative care—sectioned—living 13 lb. baby delivered: Mother died of convulsive toxemia.

Case 4.—No prenatal care—hospitalized with convulsions—delivered spontaneously—premature living child—chill on 2nd post-partum day—died on 14th post-partum day. Cause: Puerperal sepsis.

Case 5.—Two months of prenatal care—hospitalized at seven months—after ten days and with normal blood and urine, no complaints and growing restlessness she was allowed to go home although blood pressure 184 systolic—after 18 days re-hospitalization was advised but she delayed a full month longer—entered with convulsions—had three in rapid succession and died undelivered. Cause: Eclampsia and pregnancy.

The thing that impresses one in reading these case histories is that two of the patients who died had no prenatal care at all and all the others had care over too short a period of time and perhaps none of them made more than one or two visits to the clinic.

Summary

Too many women in our series had no prenatal care and too many had care over too short a period of time. Efforts to prevent the severe types of toxemia of pregnancy must be directed along the line of more adequate prenatal care.

Hospitalization of pregnant women when the signs of toxemia presented themselves afforded an opportunity for the induction of labor in 26 per cent of them and caused improvement in another 34 per cent. Less than one-fourth of the convulsions occurred in the hospitalized cases.

Convulsions occurred three times as frequently in the women without prenatal care as in those who had prenatal care.

Prenatal care should be the outstanding concern of the pregnant woman. This type of observation is a definite method of reducing the incidence of the severer types of toxemia, and absence of adequate prenatal care is a definite factor in the incidence of premature and stillborn babies.

TUBERCULOSIS AND PERSONALITY

The "Magic Mountain" personality of the tuberculous, described by Thomas Mann is symbolic of their uncertainty, mental unrest and feeling of social insecurity. It is due to the failure of the public to understand the tuberculous. Fear that the patient experiences about the attitude of others makes him depressed and nervous, gloomy and unfriendly and ashamed of his illness. The cured tuberculosis patient should have a fair chance to return to normal life.—MORTON A. SEIDENFELD, *Science News Letter*, Dec. 9, 1939.

SULFATHIAZOL IN OTOLARYNGOLOGY*

BERT G. LEVIN, M.D.

Saint Paul, Minnesota

THERAPY in otolaryngology acquired a momentous adjunct in the discovery of sulfanilimide. As in other fields of medicine there has been a two-fold sequel to the realization of its value, first in its application to an extent far greater than originally conceived, and second, a stimulation in the search for analogous drugs with specific bactericidal properties against pneumococcic and staphylococcic infections. The synthesis of the sulfapyridine derivative of sulfanilimide and its potency in pneumococcic, and even staphylococcic, meningococcic, and gonococcic infections was the forerunner to another seemingly even more valuable derivative of the parent drug.

The use of sulfapyridine in pneumococcic and staphylococcic infections has been retarded by the same kind of toxic manifestations which occur with sulfanilimide, along with a tendency to nausea and vomiting. When used in severe infections the necessarily prolonged administration plus the slow metabolism of the drug brought the side effects of vertigo, headache, malaise, and a distressing lethargy and depression. Cyanosis has been frequent, as have dermatitis, and liver and kidney damage. Neutropenia and a drop in hemoglobin have been immediate indications to discontinue use of the drug. An added disadvantage has been in two traits exhibited by the drug, first, a tendency to conjugate, with a loss of action of that percentage of the drug so acting, and second, the formation of an ineffectual acetylated derivative, both resulting in an erratic blood level.

Most of these undesirable side effects appear overcome with no loss of effectiveness in the newest derivative of sulfanilimide, sulfathiazol, the thiazole analogue of sulfapyridine, synthesized by Fosbinder and Walter²; and Lott and Bergeim.⁵ This compound, along with its methylated derivative, sulfamethylthiazol, both in vitro and in vivo action, possesses a bactericidal action against staphylococcus, streptococcus, and pneumococcus similar to sulfanilimide and sulfapyridine but has numerous points of superiority.

Herrell and Brown³ of Rochester experimented with these three drugs in connection with staphylococcus aureus growths in broth. Whereas in a control colonies were present in the ratio of 21,000 to 0.1 c.c. mixture. They were reduced to 28,000 colonies with either sulfanilimide or sulfapyridine, to 2,400 colonies with sulfathiazol, and to only fifteen colonies with sulfamethylthiazol. This checked exactly with investigations about a month ago along identical lines by Barlow and Homburger¹ who also went further in examining the action of the thiazol derivatives on Beta hemolytic streptococci and various strains of pneumococci. They found, first, that these newer compounds were 2 to 7.5 times superior to sulfanilimide in the treatment of experimental pneumococcal infections, and second, they compare favorably with sulfapyridine which, however, was determined to be 3.4 times more toxic than sulfamethylthiazol and 4.57 times more toxic than sulfathiazol.

A study of the pharmacology of these new drugs by Van Dyke, Greep, Rake,^{6a} and McKee,^{6b} reveals several significant points. Using various methods of administration and dosages in albino mice, sulfathiazol was repeatedly found less toxic than sulfapyridine. In monkeys fed sulfathiazol in dosages representing about three times the maximum human therapeutic dose now recommended there was no weight loss, where it was definite and often pronounced with sulfapyridine. None of the monkeys revealed gross or microscopic kidney damage on sulfathiazol while six or seven on sulfapyridine exhibited hematuria and albuminuria after a few days. The chronic toxic effects of sulfathiazol were less, as metabolic studies show the drug more rapidly metabolized and undergoing much less conjugation.

Sulfathiazol is found to disappear more rapidly from the blood and although the urinary excretion is the same over a twenty-four hour period, the elimination at the end of four and eight hours is double the rate of sulfapyridine. The proportion of free sulfathiazol in the blood is also greater, hence a lower blood concentration may be effective. The equal effectiveness as

*Read before the Minnesota Academy of Ophthalmology and Otolaryngology at Saint Paul, Minnesota, April 12, 1940.

shown in other studies by the same group along with the lower toxicity and more rapid metabolism at present stamps sulfathiazol as the more desirable therapeutic agent.

The fullest application of these drugs in diseases of the ear, nose and throat still remains to be determined, but clinical experiences so far reported indicate them to be valuable agents of reasonable safety, offering an important addition in the chemotherapy of otolaryngological infections or complications of pneumococcal or staphylococcal origin. A much lower mortality in cases of staphylococcal blood stream and cerebro-spinal infections will result if preliminary reports of laboratory and human experimentation continue to be confirmed.

At present, the use of the more potent sulfamethylthiazol is advised only in patients confined to bed and never in ambulatory cases, as there is a possibility of its use being followed by peripheral neuritis, and it is best restricted as yet to the more life-threatening complications as staphylococcal septicemia, pneumonia, or meningitis or other severe infections. The sulfathiazol is suggested for staphylococcal infections including bacteremia, osteomyelitis, sinusitis, otitis media, and mastoiditis. The lower toxicity and equal efficacy suggests it also for pneumococcal infections of the ear, nose and throat and their complications. A field still to be investigated is the efficacy in gonococcal infections of the eye. Lawrence,⁴ using established methods to determine the relative effects in vitro of sulfathiazol compounds concludes that they are superior to both sulfanilimide and sulfapyridine in their bacteriostatic action on gonorrhea, as well as on pneumonia Types I, II and III.

Dosage: In general the thiazol compounds may be given in the same dosage as recommended for sulfapyridine, although its lower toxicity allows larger doses for a longer period when a rapid reaching of maximum blood concentration is desired. From 30 to 60 grains may be given as an initial dose followed every four hours, day and night, with 15 grain doses for two or three days. The amount given at each dose may be decreased and the time interval between doses lengthened in conformity with the blood concentration and the clinical progress.

In less severe cases 30 grains may be given, then 15 grains every six hours, reduced as the condition indicates. Due to its rapid excretion

regular spacing of the total daily dose is recommended. In young children, 1.5 grains per pound of body weight spaced over the twenty-four-hour period is a basic dose.

Periodic determinations of the blood concentration are necessary, a level of 5 to 7 mgs. per 100 c.c. of blood being the range recommended. These determinations can be done with comparative simplicity using the powdered drug. Regular red and white cell counts, and urinalysis are important for early signs of any untoward action of the drug.

In the presence of undesirable side effects, as peripheral neuritis, or any of the toxic reactions associated with sulfanilimide or sulfapyridine, the dosage can be reduced by half if these reactions are mild or discontinued entirely. Large doses of vitamin B complex, upward from 25 mgs. three times a day, should be given intramuscularly.

Two case reports illustrating the therapeutic effect of sulfathiazol administered in average dosage, in two cases of staphylococcal otitis media and mastoiditis follow:

Case 1.—The patient, male, a physician, aged sixty-seven, had no previous history of ear or other disease pertinent to present illness. On February 14, 1940, after exposure to a cold wind on a beach in Florida, he developed pain in the right ear. An otologist incised the right membrane tympani twenty hours after the onset of first symptoms. Serous drainage ensued for eight days, then ceased, with recurrence of fulness, throbbing, and pain. During this time sulfanilimide was being administered, with sedatives and heat to the ear. Spontaneous discharge occurred with relief of pain, then ceased intermittently, which condition prevailed when he returned here, March 8.

The patient was first seen on March 9. The ear canal contained an exudate issuing from a small central perforation in the drum around which the mucosa was nipped out. Canal walls and mastoid were normal. Temperature was normal. Mastoid radiographs at this time revealed the left process to be entirely normal; the right mastoid showed normal pneumatization but with small type of cells predominating centrally. There was a diffuse increased density in the area particularly about the auditory canal representing changes due to infection and obliterating any detail of the antrum area. Radiographs repeated several times revealed the same density extending to the outermost cells of the process.

On March 14 the discharge suddenly diminished after which there was considerable pain and fulness in the ear. X-ray therapy was administered every day, with sedation, diathermy, and general measures. Sulfanilimide was discontinued while x-ray therapy was used. On March 16 the temperature rose from

normal to 101.8, the pulse was 114, there was general malaise, headache, and temporal pain. The leukocyte count was 13,950, with 72 per cent p.m.n.s and 20 per cent lymphocytes, 5 per cent monocytes, 2 per cent eosinophiles and 1 per cent basophiles. The urine was negative. Mastoid radiographs showed about the same density as the original films of five days before. The patient was hospitalized in the evening, and the next morning the temperature was 101.4 with the leukocytes up from 13,950 to 18,950. The hemoglobin was 88 to 93 per cent throughout his illness. The ear was again draining at this time. Cultures from the aural discharge on March 17, 19 and 22 revealed staphylococcus albus. Smears on these occasions revealed practically no other identifiable organisms. Sulfathiazol therapy was instituted four hours after admission, March 16, under the direction of Dr. Wesley Spink, in 15 grain doses every four hours day and night, with no other therapy. The temperature and leukocyte count for eight days was steadily downward to normal, after which time he was discharged from the hospital. A secondary rise in the leukocyte count has been followed by a gradual return to normal. The urine was negative at all times. The only untoward effect of the drug was a mild degree of nausea on the third day at which time the dose was reduced by half, but, with relief of nausea, reestablished at the original level the next day. The concentration of the sulfathiazol in the blood was determined on the third day of treatment and at 5-6 mgs. was deemed satisfactory. The drainage ceased on the fifth day and has not recurred since. During the sixteen days of the sulfathiazol therapy, it was maintained at 15 grains every six hours for four days after leaving the hospital, then at one-half doses every six hours for four more days. Slides of the mastoid x-rays taken during the sixteen-day treatment period show the extent of the original pathology and the clearing of the mastoid cells throughout the entire process. The drum has reassumed its normal appearance and the hearing is the same as before the onset of the illness.

Case 2.—Case 2 illustrates also the rapid therapeutic effect in a previously protracted case of staphylococcal otitis media and mastoiditis.

The patient, a male, aged 12 months, was hospitalized by a pediatrician on January 24, with an acute upper respiratory infection, the right ear drum inflamed, and serosanguinous discharge in the canal. On admission the temperature was 103.4, rising to 104 the next day. The leukocyte count was 18,500, hemoglobin 48, the urine normal. Right myringotomy was done. Neoprontosil was given, 3 grains every four hours, and temperature within the next four days ranged between 99 to 101 at which latter point on the fourth day the patient was discharged.

Readmission took place February 16 with the temperature 101.8, having been between 99-100 for the intervening nineteen days. Both ears had continued to discharge intermittently during this time.

On the second hospital day the left drum was incised; then on the seventh day the right was reincised.

The temperature varied from 99.4 to 104 the first three days, then 99 to 101.8, finally going to normal by the eleventh day. The white count was 17,150, the hemoglobin was 52, 45, and 50 per cent at three-day intervals. Neoprontosil was used again during this time. The patient was discharged when the temperature became normal, but purulent drainage from both ears was present.

I first saw the patient three days after his leaving the hospital the second time. Both ears had continued to discharge and on this day the temperature rose suddenly to 104; the child appeared acutely ill, had slept poorly, refused food, and had been crying a good deal. Both ears had profuse creamy purulent discharge which welled up as rapidly as cleaned. There were no mastoid or central nervous system signs. Smears and culture revealed a mixed streptococcal, pneumococcal and staphylococcal infection with but few organisms and large numbers of pus cells.

On comparatively large doses of sulfanilimide the patient's condition improved rapidly, the temperature became normal in a few days and one ear ceased to drain in about ten days. The general condition improved and the child began to gain weight. The left ear, however, never ceased to discharge, but there were no apparent complications.

On March 30, two and one-half months after the onset of the original infection, culture of the aural discharge revealed pure staphylococcus albus. A supply of sulfathiazol becoming available, the child was placed in the hospital for the third time, for administration of this drug.

Admission temperature was 100. Sulfathiazol was instituted in dosage of $7\frac{1}{2}$ grains every four hours with no other therapy of any kind. The leukocyte count on admission was 19,200. A mastoid radiograph report by Dr. Ikeda was "mastoid cloudy; air cells rudimentary but appear filled with exudate." The temperature was normal the next day and remained so. The leukocytes four days later dropped to 10,400 and again in two days were 10,350. Hemoglobin was 55 and 52 per cent. The aural secretion quickly diminished and after four days ceased entirely. The patient was discharged April 6, on the seventh day, using a reduced dosage of sulfathiazol. The ears still remain dry, temperature normal and general condition normal.

Conclusions

1. Sulfathiazol is less toxic than sulfapyridine and offers a valuable adjunct in treatment of pneumococcal and staphylococcal infections of the ear, nose and throat.

2. Sulfathiazol has proven in two cases a safe effective therapeutic agent in staphylococcal otitis media, and mastoiditis.

3. The need for the more potent drug, sulfamethylthiazol, appears restrictable to bed patients with severe staphylococcal infections.

SIGNIFICANCE OF INHALANT ALLERGENS IN THE TREATMENT OF BRONCHIAL ASTHMA OF THE CHILD*

ALBERT V. STOESSER, M.D., Ph.D.

Minneapolis, Minnesota

A RECENT analysis of the cases attending the Pediatric Allergy Clinics has revealed interesting information of value to practicing physicians. This is especially true in connection with bronchial asthma, one of the most common of allergic diseases among children. The incidence of this disease is greater in males than in females. The hereditary tendency in asthma is very strong. There are many children with a bilateral hereditary influence and a corresponding early onset of symptoms. One-fifth of the cases start in infancy and about one-half have their origin in the preschool period of childhood. Three hundred and twenty-nine children with bronchial asthma were studied. A rather exhaustive search was made for the offending allergen or allergens. Placing the patients on any form of drug therapy was avoided as much as possible. The food allergens were found to be very important in infancy and early childhood while the inhalants were the most significant cause of the asthma in the latter part of the preschool period. An increasing sensitivity to the inhalants occurred during the school years. The pollens became very important at puberty. The food sensitivity of early life was occasionally followed in the same individual by sensitivity to inhalants which prolonged the asthma over a long period of time.²

The causative foods, inhalants, and pollens were discovered in 252 cases. In some instances the sensitivity was a single one, in other cases it was multiple.³ Fifty-eight children had at-

tacks of asthma associated with infections of the upper respiratory tract. These children had no definite indication of any sensitivity to a food, inhalant or pollen. Because tonsillitis occurred frequently in this group, the tonsils and adenoids were removed. In some of the children, the maxillary sinuses were also punctured, and tem-

TABLE I. CAUSES OF BRONCHIAL ASTHMA IN 329 CHILDREN

Inhalants and pollens	4	1.3	Unknown and potassium iodide used to treat		9	2.8

porary drainage was established by making so-called "windows" in the antrums. Thirty-eight patients obtained definite relief. The remaining twenty were not helped and a few of them were made worse by the operative procedures. The best results appeared in children of the preschool age. Ten children whose tonsils and adenoids had been removed many years before the time of admission to the clinic were considered to have asthmatic attacks based on chronic infections of the respiratory system. These children were started on vaccine therapy, the outcome of which will be reported in a future communication. Nine cases failed to respond to any form of treatment except the use of potassium iodide. This preparation produced a more or less specific result. Table I summarizes the 329 cases.

*From the Allergy Clinics and Services of the Department of Pediatrics, University of Minnesota, at the University and Minneapolis General Hospitals. Presented before the summer meeting of the Nicollet-LeSueur County Medical Society, North Mankato, 1939.

The treatment of the young asthmatic children with food allergy was made easy by the fact that elimination diets can now be made up for practically every case without producing any harm to the individual.⁴ The care of the older patients with inhalant asthma exclusive of the pollens was the most interesting. Two forms of treatment were considered. First, there was the hyposensitization therapy and second the elimination of the offending inhalant. The former was tried many times, especially in connection with house dust sensitivity. The results were very discouraging. In three cases, the inoculations precipitated a generalized eczematous eruption. All these children had had eczema during infancy. The elimination of the offending inhalant from the environment of the allergic child gave the best results. The ease with which this could be done depended on the inhalant involved. The incidence of sensitivities to the various inhalants is given in Table II.

TABLE II. VARIOUS INHALANTS CAUSING ASTHMA IN 122 CHILDREN

	No. cases	Per cent		No. cases	Per cent
House dust	33	27.0	Orris root	5	4.1
Feathers	27	22.1	Cat dander	3	2.5
Cottonseed	20	16.4	Silk	3	2.5
Horse dander	14	11.4	Glue (fish)	3	2.5
Cow dander	6	4.9	Kapok	2	1.7
Dog dander	5	4.1	Wool	1	0.8

The children sensitive to house dust were hard to handle in many instances. These patients gave strong reactions to house dust and very weak or no responses to feathers, cottonseed, hairs, wool or other allergens in the home. The active principle of house dust was not determined and the removal of this inhalant from the child's environment never was complete. As a result the children would have periods of relief which were terminated by sudden attacks of asthma. These attacks might be of short duration but often the asthma became progressively worse so that for a few days the child was very ill, and the duration of the period of convalescence was about one week. It was soon observed that the clinical manifestations to house dust varied with the amount of the inhalant in the child's home. Even when simple procedures were carried out, the response was most encouraging. Instructions were given to parents to prevent the child from being too active in the house. Jumping

up and down on upholstered furniture often caused wheezing. Cleaning with a vacuum cleaner was prohibited, especially in the presence of the allergic patient. The removal of heavy drapes, rugs, pillows, and over-stuffed furniture was recommended. If this could not be made to apply to the entire home, a section of the house, or at least the bedroom, was arranged to fit the recommendations. A visit to the home by the physician to check the improved conditions was helpful.

The feather sensitivity was taken care of quite easily. All pillows, mattresses, cushions, upholstery and quilts containing feathers of any kind were removed from the house. Birds, such as canaries or parrots, were not permitted in the home. The child on the farm, who was found sensitive to feathers, was watched closely by his parents in order to prevent his contact with the domestic fowl. On occasions when the patient disobeyed and entered the poultry pen, he became the victim of a violent asthmatic attack. Often this was a clear warning to the parents of the extreme sensitivity of their child to feathers.

The children with the cotton or rather cottonseed sensitivity were most interesting. At first very little progress was made with these cases, but as more and more information was obtained concerning the various uses of cotton in the home the physicians were better able to cope with the problem, and soon more satisfactory results were noted. The sensitivity to cotton is in the average case due to the protein of the husks and the protein of the cottonseeds, the former protein being considered by some writers to be the most irritating of the two. Dust made up of minute particles of the cottonseed can penetrate into the deepest part of the lungs, thereby quickly producing an irritation. Only those individuals extremely sensitive to cotton give reactions to the fiber, free of the cottonseed.

The source of cottonseed dust in the home is linter cotton. After the ginning machine removes the lint, there remains about the cottonseed a woolly covering of short fibers which is known as fuzz. When this is removed by the seed-delinting machine, it is called linters. The material varies in color, ranging from gay, yellow and green to brown. The color depends largely on the closeness of the cut. The more fuzz that is removed from the seed, the darker is its color because the fuzz is darkest near the

seed. The color of the linters is also darker when there is much dust and other foreign matter present.

The treatment of the children sensitive to cottonseed (Fig. 1) was the removal of as much linter cotton as possible from the patient's environment. In the home this material was found in mattresses, studio couches, day-beds, upholstered chairs, cushions, pads and comforters. The cheaper articles of furniture contained the poorer grades of the dark brown linters. Mixed with it was a large number of small particles of the cottonseed. The elimination or reduction of the dust arising from the seed particles was handled in three ways. First, an attempt was made to remove as much of the furniture containing linters cotton as possible from the child's environment. Second, dust-proof covers were recommended for certain articles of furniture. Third, special mattresses and cushions were obtained when the purchase of new furniture was made. The first recommendation was especially directed toward the removal of old worn-out pieces of furniture in which the cottonseed of the linters had been pounded into a fine dust from years of service and in which there was also a danger of mold growth, emphasized by some writers as an added factor in connection with cotton sensitivity. The dust from the furniture was considered to be a more potent allergen as the furniture, and therefore linters, became older. It was most important to remove this furniture from the child's bedroom and if practical from other parts of the house.

The dust-proof covers were recommended for mattresses, pads and cushions. The parents were given two specific directions: one, to make airtight encasings for these articles by sewing them on or closing them with a zipper rather than merely wrapping them with covering material, and two, to use cloth impregnated with the new synthetic rubber-like preparation instead of cloth coated with a thin layer of real rubber, for the latter does not wear well, eventually cracks, and thereby permits the escape of dust. On the other hand, the synthetic rubber wears well, withstands heat and perspiration, and has the advantage of being washable.

The special mattresses and cushions were made of materials which were not considered to be important allergens. A fairly thick layer of sisal was placed over the inner-spring type of

construction, and the sisal was covered by a good grade of clean cotton, containing a few remnants of leaves but no cottonseed and referred to by some mattress manufacturers as staple cotton.

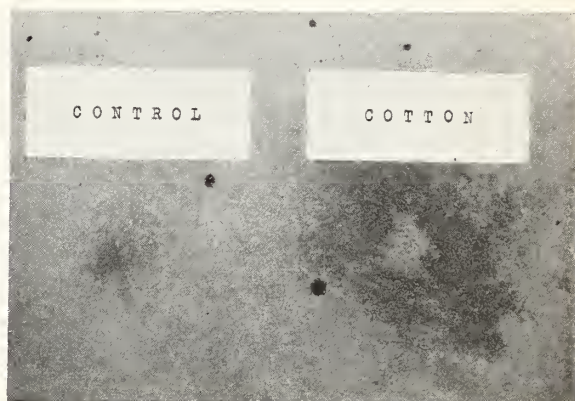

Fig. 1. Typical pressure-puncture skin test reaction to the cotton-cottonseed extract in a child with bronchial asthma, who improved at once when linter dust was removed from his environment.

This type of mattress was not expensive and its construction indicated that it would withstand years of service. The new foam sponge (rubber) mattresses and cushions were not overlooked. They were, however, found to be more expensive than the special cotton articles of furniture, and their durability was still being questioned.

The children sensitive to animal emanations did not present a difficult problem. Most of these patients came from the rural districts and arrangements were made to keep them in the larger towns or cities away from the farm animals. Occasionally the parents were not convinced that this was the best form of treatment and so the child was allowed to go home, where he soon developed another asthmatic attack. When this occurred, the patient was gladly returned to the city. Here the only danger was the dog and the cat. These animals were always promptly removed from the child's environment.

The patients who gave marked reactions to orris root, silk, kapok and wool responded favorably when these inhalants were removed. Not much difficulty was encountered. There were two observations made in connection with orris root in that some of these children became violently ill after being in a theater and others did not do well until every member of the family had started using non-allergic cosmetics.

The children with fish-glue sensitivity were

hard to treat. Removal of old books and other articles made with or from glue did not help. Hyposensitization was tried and the results were encouraging. Further studies are indicated, however, before any definite conclusions can be made.

Finally the relationship of weather changes to the attacks of asthma was observed. Some physicians have felt that weather had no influence on the asthma; others have accepted the statements of the parents that sudden changes in weather do precipitate attacks of asthma, and this clinical belief has been confirmed by the recent work of Preuner.¹ He showed that in experimental asthma in guinea pigs a measured amount of an excitant produced a greater degree of asthma in a shorter period of time when weather conditions were changing than when they were constant. Thirty-seven of the children had asthmatic attacks with practically every sudden change in the weather in spite of the fact that measures had been instituted to make them free of asthma during the interim. Twenty-five of these patients were sensitive to inhalants, five were pollen asthmatics, three had food allergy and four were considered to have chronic infections. The majority of cases sensitive to inhalants gave reactions to house dust. Probably the fact that this allergen could never be completely removed from the child's environment predisposed to his susceptibility to the weather changes.

Summary and Conclusions

1. An analysis was made of 329 children with asthma attending the Pediatric Allergy Clinics at the University and Minneapolis General Hospitals.

2. The inhalant group of allergens exclusive

of the pollens was the cause of asthma in the largest number of children. House dust, feathers and cottonseed were the most important inhalants.

3. Hyposensitization therapy for the inhalant allergy did not give encouraging results.

4. The children sensitive to house dust were difficult to treat because this inhalant could be reduced but not completely removed from the environment.

5. The cases sensitive to feathers responded well to the thorough removal of the inhalant.

6. At first the children sensitive to cottonseed presented a difficult problem, but with the reduction or elimination of the linter dust from the environment good results were obtained. To take the place of some of the articles of furniture containing linter cotton, special mattresses and cushions were ordered to be made up of materials considered to be very weak allergens.

7. The patients sensitive to animal emanations and some of the other inhalants were easily taken care of by more or less routine measures. The only exception was in connection with the fish-glue sensitivity. The children sensitive to this allergen required the hyposensitization therapy, the results of which were fairly good.

8. Sudden changes in the weather did have some influence on the asthma, especially in children sensitive to house dust.

EWING'S TUMOR (HEMANGIO-ENDOTHELIOMA; ENDOTHELIAL MYELOMA; SOLITARY DIFFUSE ENDOTHELIOMA): A PROBLEM IN DIFFERENTIAL DIAGNOSIS*

HENRY W. MEYERDING, M.D., F.A.C.S., and GEORGE A. POLLOCK, M.B., F.R.C.S. (Ed.)

Rochester, Minnesota

PRIOR to 1922, Ewing's tumor was considered by some surgical pathologists as a round-cell sarcoma of bone. In the years that followed, this type of tumor became more readily recognized

due to its peculiar clinical behavior and its specific reaction to irradiation. The tendency of this tumor to destroy bone, periodicity of symptoms with complete remissions of pain and its almost characteristic roentgenologic appearance have all received attention by various authors when reporting the subject. As a result, in re-

*From the Section on Orthopedic Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 18, 1939.

cent years, the profession has been stimulated in its investigations of the condition.

It has been our experience that to distinguish between Ewing's tumor and osteomyelitis is of great importance; in the earlier phases this problem is more difficult than in the later ones. The seriousness of distinguishing between a malignant neoplasm and a benign inflammatory lesion is obvious; errors in diagnosis continue to occur, however, taking their toll in human life and suffering. An illustration of the status of diagnosis of Ewing's tumor shortly after the original description of the condition by Ewing is demonstrated in our first case to be reported.

That Ewing's tumor is not the pathologic rarity, among malignant bone tumors, that it is generally believed to be, is shown in a recent review of malignant tumors made by one of us (Meyerding). From this study, it was shown that Ewing's tumor (endothelial myeloma) formed 26.9 per cent of the primary malignant lesions of bone. In one case out of every 7,666 encountered at the clinic, the diagnosis of Ewing's tumor was made; no doubt it is possible that its occurrence in the general practice of medicine is even less frequent.

While the disease may evince itself in those persons of more advanced years, like osteomyelitis it tends to occur more commonly in the younger age groups. In our series of 114 cases of Ewing's tumor, 66.8 per cent of the patients were less than thirty years of age. Males are undoubtedly more prone to be the victims inasmuch as 71.9 per cent of the patients were males; 28.1 per cent were females. The middle of the shaft of long bones is the site of election and of all the bones affected the femur appears to be the one most commonly involved. The probable localizing factor, if we can speak of it as such, is trauma, a fact which is true for osteomyelitis, also. When dealing with young subjects, however, it is exceedingly difficult to assess accurately the true degree and value of an injury, as this is so common an occurrence in adolescence. Frequently in cases of Ewing's tumor, the patient is able to describe a definite and related injury (35.1 per cent), prior to the occurrence of swelling and pain in the limb, subsequently proved to be the site of tumor formation. Thus, some consideration must be accorded to trauma as an etiologic factor. Pathologic fracture as the initial symptom of this disease is not a common

occurrence, although as a late complication it may be present, constituting 15.8 per cent of those in our series of cases.

Pain is the early and most characteristic symptom of osteomyelitis and Ewing's tumor. Although at first vague and transitory, it becomes severe and constant in the later stages. Nocturnal exacerbations render sleep fitful or even impossible and contribute, with toxemia, to the lowered health and general "run-down" appearance of these patients. The pain of any acute infectious process tends to be constant, throbbing and progressive and in these features we have points which sometimes help in making a diagnosis, since the pain of a Ewing's tumor usually shows intermissions which vary from days even to months. Swelling of the part with local tenderness to pressure and an elevated oral and local skin temperature are common to both conditions but in cases of osteomyelitis the ranges of fever are usually greater and hectic in type. Local edema and reactionary synovitis of the neighboring joints are suggestive of an acute infective process rather than of a tumor. Blood investigations do not help much since both may be associated with a variable degree of deficiency of hemoglobin and in both a definite leukocytosis may occur. Occasionally, however, a positive blood culture will aid in arriving at a diagnosis of the true infectious nature of the illness even when roentgenologic evidence is lacking.

Acute rheumatic fever in its early stages may simulate either osteomyelitis or Ewing's tumor but a distinction should be comparatively easy owing to the flitting character of the joint involvement, the very characteristic response of the joint pain to the administration of sodium salicylate and the lack of roentgenologic signs in the former condition.

If the patient is a youth who complains of persistent or recurrent attacks of pain in the course of a long bone, particularly if the pain is worse at night, we must not be satisfied by a primary roentgenologic examination that results in negative findings. Repeated roentgenologic examinations should be made at regular intervals until the early destruction of bone and periosteal reaction are recognized or until a sufficient period has passed to render the presence of a new growth improbable. Only by frequent examinations at regular intervals can we hope to improve our average of early

diagnosis and perhaps also render the end results of treatment more hopeful. We must not forget that although the roentgenologic appearances may be characteristic in certain cases, they may confuse the issue in others. Figure 1 shows the radiologic characteristics of osteomyelitis of the femur, yet biopsy revealed the underlying process to be a Ewing's tumor.

Ewing's tumor begins in the endothelium of the blood vessels in the medulla of the bone and the bone becomes widened owing to invasion of the cortex, which becomes moth-eaten in appearance. A reaction of periosteal proliferation occurs with deposition of successive layers of new bone, as each in turn is destroyed by the advancing tumor process. It is this formation which gives to the roentgenograms the onion-layer-like appearance described in the literature. Although characteristic, this onion-layer-like appearance is not pathognomonic, for a similar reaction may occur in cases of osteomyelitis and, more rarely, in cases of osteogenic sarcoma.

When doubt exists as to the true nature of the lesion, a fresh frozen section should be examined microscopically. Microscopic diagnosis is one of the most certain methods for the identification of malignant lesions but it must be remembered that, on occasion, even a skilled surgical pathologist may have difficulty in arriving at a definite diagnosis. When this occurs, the surgeon must be certain that he has removed tumor tissue; it is advisable for the surgical pathologist to be present at the operation so that he may observe the site from which the specimens are taken. The surgical pathologist selects the tissue that is most likely to give a characteristic appearance microscopically. Not infrequently, at operation, a milky purulent-like material exudes as the tumor is incised and the surgeon concludes from this that he is dealing only with osteomyelitis. When this is associated with fever, leukocytosis and perhaps an indefinite microscopic appearance, it is easy for even an experienced surgeon to be misled unless he is on the lookout continually for just such an occurrence.

A confirmatory diagnosis, without recourse to surgery, may be obtained by means of therapeutic irradiation. Desjardins has maintained that the rapid melting away of these radiosensitive tumors under the influence of irradiation is an even more accurate test for Ewing's tumor than is

biopsy. We have observed several cases in which the pathologic diagnosis of inflammation proved to be erroneous and irradiation led to rapid destruction of the tumor.

In the treatment of Ewing's tumor, our methods of attack vary with the site of the tumor and the length of time that the condition has been present. The presence of metastatic lesions in the lungs precludes radical surgery in that it indicates an unfavorable prognosis. Roentgen therapy, however, can be used in an endeavor to relieve the pain from which these patients suffer. No doubt it was in cases such as these, in which the prognosis was poor if not completely hopeless, that irradiation had its first opportunity to challenge surgery, and the favorable results which followed in certain instances demonstrated the undoubted therapeutic value of this new method in our fight against malignancy. When irradiation therapy is used for tumors of the pelvic girdle, the patients should be forewarned of the possibility of a resultant sterility. Lead therapy has been used in cases in which the patients had a diagnosis of malignancy, but we have had insufficient experience with it to permit of our passing judgment as to its value in cases of Ewing's tumor.

Amputation because of tumor formation, unfortunately, is an admission of defeat; we admit our inability to destroy the growth successfully. When it is employed, it is done in the hope of obtaining a cure or as a palliative measure. There was a time when it was our tendency to treat the tumor by excision and irradiation, but at times the site or size of the tumor made even excision a hazardous undertaking. While the prognosis in cases of Ewing's tumor is almost uniformly bad when secondary tumor deposits are found in the lungs, the possibility of some benefit being derived from the use of Coley's toxins should be given due consideration. In "The diagnosis and treatment of Ewing's tumor" one of us (Meyerding) reported an interesting case. A girl, eleven years of age, had Ewing's tumor which had been diagnosed following microscopic examination, and for which treatment was by means of irradiation and Coley's toxins only. She is still alive about eleven years following the original treatment. The occurrence of what at this late date may be called a cure is an additional incentive to treat these patients conservatively rather than to submit them to mutilating operations.

Report of Cases

Case 1.—A boy, aged five years, registered December 19, 1923. He related that he had fallen from a horse eight months prior to this time, that there had been no disability as a result of the accident but that six months later he had begun to limp and to complain of pain in the region of the right hip. Four days prior to registration or approximately eight months following the injury, he had been awakened from sleep and since then had cried nightly because of pain.

On examination, complaint of pain was elicited on pressure over the greater trochanter of the right femur. The Wassermann blood reaction was negative, as was the Mantoux tuberculin test, but the von Pirquet test was reported as giving a questionable positive reaction. Leukocytes numbered 12,600 per cubic millimeter of blood; 7.5 per cent were eosinophils. The tonsils were enlarged. Roentgenologic examination of the thorax gave negative results; the lesion of the right femur was reported by the roentgenologist as osteomyelitis of the neck and of the greater trochanter (Fig. 1). It is of interest to note that the clinician who saw this patient also considered the condition to be osteomyelitis, whereas the consulting orthopedist thought that it might be tuberculous in nature.

At the time of operation, February, 1924, the surgeon was unable to determine the exact nature of the lesion from the gross appearance and he sent a portion of the tissue for microscopic diagnosis. The pathologist also deferred giving an immediate opinion until he had studied the microscopic appearance more thoroughly. Two days later a diagnosis of round-cell and oval-cell sarcoma was made by the surgical pathologist and the patient was sent for irradiation therapy. In April, 1924, further irradiation was given in the region of the groin and hip. The roentgenograms taken at this time, or two months postoperatively, were reported as showing osteitis of the neck and greater trochanter of the right femur. In May, 1924, the patient became very ill and the roentgenologic examination of the thorax revealed the presence of metastasis. Irradiation of the lungs was performed. The patient died two months later with metastasis to the skull and lungs. A re-examination of the tissue was made, in 1939, by Dr. Broders, who reported hemangio-endothelioma, grade 4 (Ewing's tumor).

Case 2.—A boy, aged twelve years, was admitted at the clinic on October 28, 1930, with a history of pain in the region of the right hip of five months' duration, which became associated with a limp two months later. He stated that the pain was dull and aching in character and that it occurred periodically, sometimes in the hip and at other times in the thigh and knee. Between the attacks of pain, he was completely free of symptoms. Damp weather aggravated his pain and at times his temperature had been 102° F. (38.8° C.). Interrogation elicited the fact that one month prior to the onset of the pain, or six months prior to his admission, he had fallen with the thigh in an abducted position and had suffered severely at that time, although recovery occurred within a few days. The father

stated that prior to coming to the clinic a diagnosis of tuberculous osteomyelitis had been made.

Examination revealed a fullness over the proximal anterior aspect of the right femur and the veins in this region were engorged. Fluctuation could be de-

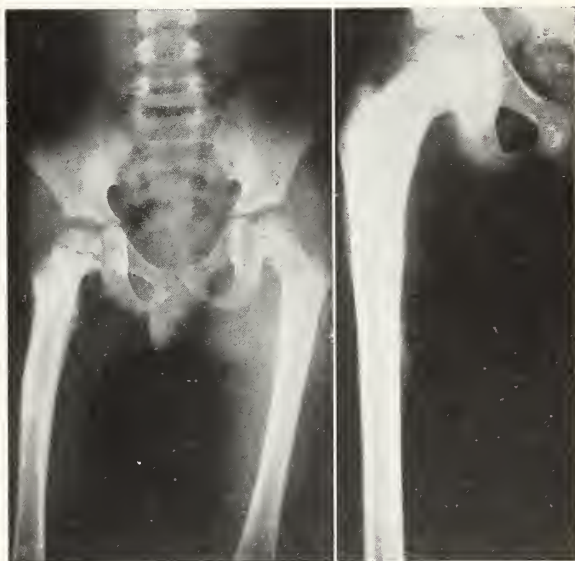

Fig. 1. (left) Anteroposterior view demonstrating Ewing's tumor of right femur which had been roentgenologically diagnosed as osteomyelitis. The clinical diagnosis was osteomyelitis and the microscopic diagnosis was round-cell and oval-cell sarcoma.

Fig. 2. (right) Ewing's tumor of the portion of the upper right femur. Note the periosteal thickening and masking of the medullary cavity with moth-eaten appearance.

tected and a diminution in the range of movement was noted. The tonsils were injected. The Wassermann blood reaction was negative. The leukocytes numbered 4,800 per cubic millimeter of blood. A roentgenologic diagnosis of Ewing's tumor was made and as the roentgenograms of the thorax were normal, operation was advised for microscopic confirmation of the clinical and roentgenologic opinions (Fig. 2). On October 31, 1930, a biopsy was performed and a fresh frozen section was studied. A diagnosis of Ewing's tumor was made. Irradiation was carried out in November and December, 1930, and in February and April, 1931. In February, 1931, the limp and swelling had practically disappeared and the thickened periosteum, evidence of which had been obtained previously on roentgenologic examination, had almost disappeared. In April, 1931, because of a suspicion of early metastasis, irradiation therapy was given over the region of the thorax. Clinically, however, the child was healthy. His leg moved normally, the circumferences of both thighs were alike and the roentgenograms of the femur were reported normal. His weight at this time was 83 pounds (37.7 kg.).

In August, 1931, the roentgenograms of the thorax and femur, taken elsewhere, were sent to us for an opinion; both were normal. In March, 1938, the patient reported by letter that he was in good health, which was almost eight years following the onset of symptoms.

Case 3.—A male student, aged eighteen years, registered at the clinic on July 28, 1934. He related a history of an injury, which had occurred while playing with friends about four months prior to registration, since which time he had noticed an intermittent, dull,

through 36 mm. of aluminum. Following treatment there was rapid improvement in symptoms and destruction of the tumor.

This patient has been under our observation for a period of five years and has remained well, has car-

Fig. 3. The left humerus; *a*, four months following injury and before treatment; lamination (onion-layer appearance), thickening of the periosteum and masking of the medullary cavity are evident. A diagnosis of Ewing's tumor was made; *b*, following irradiation, marked improvement is apparent.

aching pain in the shaft of the left humerus which caused no particular discomfort until six weeks prior to admission. At that time he said that the pain had become more noticeable and he was able to palpate a fusiform mass in the shaft of the humerus and that during the month prior to coming here, he had had a temperature as high as 100° F. (37.7° C.) with occasional sharp flashes of pain projecting down the arm, increase in the size of the swelling and some loss of weight.

Examination revealed a well developed and well nourished young man, whose height was 5 feet 11 inches (177.5 cm.) and whose weight was 165 pounds (75 kg.), and whose blood pressure, pulse rate and temperature were all within normal limits. There was a fusiform mass that involved the shaft of the left humerus which was tender and at which point there was apparently some fluctuation. The circumference of the upper portion of the left arm was 1.5 inches (3.8 cm.) greater than that of the right. Palpation disclosed increased temperature over the region of the tumor. The roentgenograms of the thorax were normal. The urine and blood were normal and a flocculation test on the blood for syphilis gave negative results. A clinical and roentgenologic diagnosis of Ewing's sarcoma (Fig. 3) was made and the patient was referred to the Section on Radiotherapy for irradiation. He received four courses of treatment, over a period of two years, of moderate voltage technic with 135 peak filtered

ried on his work and has had no evidence of local recurrence of the tumor or of metastasis.

Case 4.—A boy, aged five years, was brought to the clinic on August 27, 1934. There was a history of pain in the right thigh of ten months' duration. Three months prior to the onset of the pain the child had fallen from a tricycle and had bruised the upper portion of the right thigh. The pain had been intermittent and was principally present at night accompanied by a temperature of 99° F. (37.2° C.), malaise and marked anorexia. Roentgenograms had been taken and had been reported negative. On two occasions prior to his registration, the patient had been operated on and a diagnosis of staphylococcal osteomyelitis had been made; the wounds had been Dakinized on these occasions. The symptoms recurred following each operation, however, and the wounds had healed rapidly.

Examination at the clinic disclosed enlargement of the upper part of the right thigh; locally the part was hot and the patient had a temperature of 100° F. (37.8° C.). The roentgenologist suggested the diagnosis of Ewing's tumor possibly with a fracture (Fig. 4). Roentgenologic examination of the thorax gave negative results. The urine was normal. The blood contained 10.3 gm. of hemoglobin per 100 c.c. and the leukocytes numbered 10,600 per cubic millimeter. The various forms of treatment of this condition, consisting of amputation, irradiation and biopsy, were thoroughly discussed with the father. It was decided that he would return home to the care of his attending
